ServiceNow Vault overview

ServiceNow Vault is a set of data security tools that protect sensitive information from unauthorized access, corruption, or theft throughout its entire life cycle. You can use ServiceNow Vault to apply protections like encryption, continuous authentication, and data privacy for the redaction and auditing of sensitive information.

Note:

ServiceNow Vault is a paid plugin that ServiceNow personnel must activate on your production instance. ServiceNow Vault includes the components listed here.

To purchase a subscription, contact your ServiceNow account manager. When you purchase a subscription, certain plugins are activated automatically. If a paid plugin isn't activated automatically, you can manually activate it from the **All Applications** list in your instance.

ServiceNow Vault benefits

ServiceNow Vault benefits

Cloud Encryption and Field Encryption with Key Management is a suite of highly configurable encryption modules

Help improve security by validating sensitive application configuration data and scripts before they are used.

Data Privacy

Use the Data Privacy plugin to remove personally identifiable information (PII) from user data when it is migrated from a production instance to a non-production instance.

Data Discovery

The Data Discovery plugin enables you to find personally identifiable information (PII) from user data. The data can then be classified for further security measures.

Log Export Service

Improve security, performance, and user experience by exporting ServiceNow log data into enterprise log analytics using the log export service.

Zero Trust Access

ServiceNow Session Access enables organizations to dynamically reduce user privilege in a web session

Vault Suite

Vault Suite deploys the complete set of ServiceNow Vault capabilities on your instance automatically, eliminating manual plugin setup.

Vault Suite is available on the ServiceNow Store. When you install Vault Suite, all included capabilities are activated on your instance automatically. You don't have to install each capability separately.

Vault Suite includes the following capabilities:

Vault Suite capabilities

Capability	Plugin ID	Description
Vault Console	Store app (Scope:sn_vault_console)	Unified administration dashboard for managing and monitoring all Vault Suite capabilities.
Data Privacy	Store app (Scope:sn_dp_store_app)	Discovers, classifies, and anonymizes sensitive data to

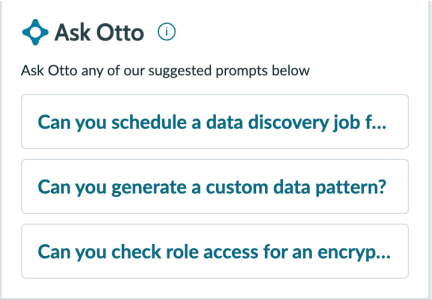
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Vault Suite capabilities (continued)

Capability	Plugin ID	Description
		prevent leakage during clone, fulfill Right to Be Forgotten requests, and mask PII across platform channels.
Code Signing	com.glide.code_signing_enterprise	Verifies the integrity of code artifacts on the platform.
Field Encryption	com.glide.field.encryption.enterprise	Provides unlimited field and attachment encryption with customer-managed key support.
Zero Trust Access — Continuous Authentication	com.snc.zero_trust_continuous_authentication	Requires continuous re-authentication when users access sensitive data.
Zero Trust Access — Location	com.snc.zero_trust_location_access	Restricts access to classified data based on user location.
Zero Trust Access — Session Access	com.snc.zero_trust_session_access	Controls access to sensitive operations at the session level.
Log Export Service	com.sn_logstoanalytics	Forwards instance logs to external analytics platforms.
Cloud Encryption	com.glide.platform.cloud_encryption	Encrypts data at rest at the cloud platform level. **Note:** Cloud Encryption is not installed automatically with Vault Suite because the product plugin is installed when a new instance is provisioned. To add Cloud Encryption to a previously provisioned instance, see KB1117369.

Note: To install Vault Suite, check your entitlements to determine whether you have the ServiceNow Vault subscription, then request it from the ServiceNow Store. For installation steps, see Install Vault Suite.



AI in ServiceNow Vault

With the ServiceNow Otto for Vault application, you can automate many tasks in Vault with the help of AI. These tasks include securing custom applications to improve your security posture, checking role access for an encrypted column to instance's encryption access posture, and others.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

ServiceNow Otto panel in ServiceNow Vault console

The ServiceNow Otto panel in ServiceNow Vault console lists common security tasks. Selecting a task opens a conversational interface that lets you accomplish the task through prompts. For more information about the ServiceNow Otto conversational interface, see ServiceNow Otto panel.

Configuring ServiceNow Vault

Learn how to install and configure ServiceNow Vault.

Configuration overview

- Install ServiceNow Vault

  Install the ServiceNow Vault application and assign the required roles to users who need access to the Vault console.

- Install Vault Suite

  Install all ServiceNow Vault capabilities in a single step, from either the Application Manager or the ServiceNow Vault tile on Admin Home.

- ServiceNow Vault roles

  Learn about the roles necessary to use ServiceNow Vault and elevate to them so that you can access the full range of Vault capabilities.

- Install Vault plugins

  Install and verify the plug-ins needed to make the most of ServiceNow Vault.

- Install ServiceNow Otto for Vault

  Install ServiceNow Otto for Vault to make use of generative and agentic AI capabilities within ServiceNow Vault.

Using guided setup to implement ServiceNow Vault

Guided setup provides a sequence of tasks that help you configure ServiceNow Vault on your ServiceNow instance. To open guided setup for ServiceNow Vault, navigate to **All** > **Vault** > **Vault console**.

For more information, see Use guided setup for ServiceNow Vault.

Install ServiceNow Vault

Install the ServiceNow Vault application and assign the required roles.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin
Role required: admin

About this task
When you first navigate to the Vault console on a new instance, the console is in preview-only mode. To activate full functionality, install the Vault console application from the ServiceNow Store or Application Manager. After installation, Data Discovery is available by default. All other tools require separate configuration.

Note:

To install all ServiceNow Vault capabilities without configuring each plugin separately, see Install Vault Suite. If your instance has a ServiceNow Vault entitlement, that topic also covers installing from the ServiceNow Vault tile on Admin Home.

Procedure

1. Install ServiceNow Vault by going to the ServiceNow Store and selecting **Buy** .
   Alternatively, you can also complete installation by navigating to **All** > **Application Manager** > **Vault Console**.
2. Elevate to the `security_admin` role by selecting your profile icon and then selecting **Elevate Roles**.

   A dialog box appears that contains available roles for elevation. In this case, you can check security_admin and select **OK**.
3. Assign the `sn_vault_console.vault_console_admin` role to the user that would need access to the Vault console by performing the following:
   a. Navigate to **All** > **User Administration** > **Users** and then open a user record.
   b. In the **Roles** related list, select **Edit**.
   c. In the **Collection** list, select the sn_vault_console.vault_console_admin role, and then select **Add**.
   d. Select **Save**.
4. Based on organizational needs and functionality of each user, further additional tool-specific roles can be assigned to users.
   For more role related information, see ServiceNow Vault roles.

Install Vault Suite

Use Vault Suite to deploy ServiceNow Vault and its underlying plugins in a single step, without configuring each plugin separately.

Before you begin
Your instance must have a ServiceNow Vault entitlement. Without an entitlement, the underlying plugins remain inactive after installation and the tool cards on the ServiceNow Vault console dashboard appear as inactive.

Role required: admin

About this task
Vault Suite includes ServiceNow Vault and its premium plugins, including Data Privacy, Log Export Service, Zero Trust Access, Field Encryption, and Code Signing. Installing Vault Suite activates all included plugins together.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note: If ServiceNow Vault is already installed on your instance, installing Vault Suite adds the remaining plugins without affecting your existing ServiceNow Vault configuration.

You can install Vault Suite from the Application Manager or from the ServiceNow Vault tile on Admin Home. Both entry points use the same Application Manager installation process and install the same plugins. However the ServiceNow Vault tile appears on Admin Home only when your instance has a entitlement.

Procedure

1. Navigate to **All** > **Application Manager** > **Vault Suite**.

   Alternatively, go to Admin Home, select the ServiceNow Vault tile, and then select **Start new setup** to open the ServiceNow Vault product hub page.

2. Select **Install**.
   Vault Suite begins installing the underlying plugins. Installation may take several minutes to complete.

   If you install from Admin Home, Vault Suite moves to the **Installed** tab on the product hub page when installation completes.

Result

Vault Suite and the following premium plugins are installed on your instance:

- Vault Console
- Data Privacy
- Log Export Service
- Zero Trust Access
- Field Encryption
- Code Signing

What to do next

Navigate to the ServiceNow Vault console dashboard to confirm that the tool cards are enabled. On Vault Console 2.1 or later, if your instance doesn't already have policies or configurations for Anonymization and Log Export Service, then ServiceNow Vault can apply ready-to-use defaults to help you get started. For more information, see Default policies and configurations in ServiceNow Vault.

If you installed from Admin Home, select **Configure** on the product hub page to open the Configuration Console for ServiceNow Vault. In this release, the Configuration Console provides **Open Vault Console**, which navigates to the ServiceNow Vault console dashboard. You can also mark the product as configured to record your progress, which doesn't change any configuration.

Note:

To use the full range of ServiceNow Vault capabilities from the ServiceNow Vault console dashboard, elevate to the roles described in ServiceNow Vault roles.

ServiceNow Vault roles

Learn and set up the roles necessary to use ServiceNow Vault.

To use ServiceNow Vault and its capabilities, elevate to the roles in this table by selecting your profile icon and then selecting **Elevate role**. The `security_admin` role is not available

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

in the Elevate role list; a user with the admin role must assign it through the standard user-administration process.

Role	Description
`sn_vault_console.vault_console_admin`	This role is necessary to view the Vault console dashboard and use guided setup in your instance. It is a combination of Data Classification admin, Data Privacy admin, and CA admin roles for management of the Vault console. On the Vault console dashboard, this role provides read-only access to all the tool charts and available protection configurations. This role includes `access_analyzer_ai_user`, which AI agents require to call the Access Analyzer API.
`ca_policy_admin`	This role is necessary to create, edit, and view Continuous Authentication (CA) policies.
`ca_admin`	This role is necessary to create, edit, and view CA policies, configure CA properties, and access CA dashboards and metrics.
`data_privacy_admin`	This role is necessary to create technique and policy configurations. Doesn't include access to create, read, or view jobs.
`data_privacy_processor`	This role is necessary to create, read, update, and delete user-based jobs.
`data_privacy_clone_processor`	This role is necessary to create, read, update, and delete dataclass-based jobs.
`security_admin`	This role is required to modify high-security settings and manage the Access Control List (ACL). On the **Protect existing data** screen in guided setup, this role is required to create or modify field encryption configurations.
`sn_vault_console.vault_console_read_only`	Provides read only access to the Vault console. Use this role to review data classification and protection policies without modifying configurations. On the **Protect existing data** screen in guided setup, this role provides read-only access to available protection configurations. This role includes `access_analyzer_ai_user`, which AI agents require to call the Access Analyzer API.

Note: The `security_admin` role was removed from the `sn_vault_console.vault_console_admin` role composition for security reasons. It no longer appears in the Elevate role list. A user with the admin role must assign `security_admin` through the standard user-administration process. To assign roles related to Field Encryption such as `sn_kmf.admin` and `sn_kmf.cryptographic manager`, contact your admin. For more information, see Role requirements for Field Encryption.

Install Vault plugins

Learn how to review and install the necessary plugins for ServiceNow Vault.

Before you begin

Role required: Elevate to sn_vault_console.vault_console_admin role.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

ServiceNow Vault is best used with other ServiceNow security products. Make the most of your tools and metrics by installing and configuring the plugins listed in step 3.

Procedure

1. Navigate to **All** > **Vault** > **Vault Console**.
2. Review the status of your tools.

Tool statuses

Status	Description
Limited access	Tool has a limited access license. Reported metrics may be affected or unavailable.
Included with platform	Tool is included by default with the platform
Needs license	Tool has no license. Reported metrics may be affected or unavailable.
Premium license	Tool has full access.

3. **Optional:** If a status is either limited or needs a license, review its respective installation page.

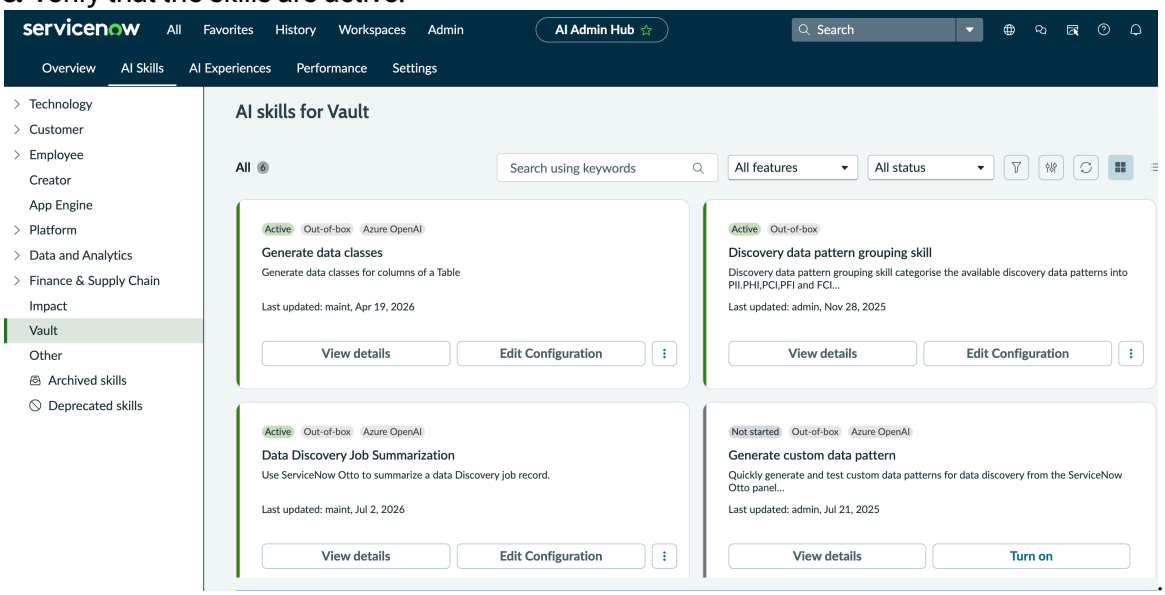
Tool installation

Tool	Installation page
Data Discovery	Activating Data Discovery
Data Classification	Included with the platform.
Data anonymization	Activate data privacy **Note:** Data anonymization is installed as part of Data privacy.
Cloud Encryption with Key Management	Requesting Cloud Encryption for instances with Now Support Service Catalog [KB1117369] article in the Now Support Knowledge Base
Field Encryption	Activate Field Encryption
○ Zero Trust Access (ZTA) ○ Continuous Authentication (CA)	○ Activating Zero Trust Access ○ Activating Continuous Authentication

Install ServiceNow Otto for Vault

Install the ServiceNow Otto for Vault application from the ServiceNow® Store to get AI capabilities within Vault.

Before you begin



Review the ServiceNow Otto for Vault application listing in the ServiceNow Store for information on dependencies, licensing or subscription requirements, and release compatibility.

Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. From the ServiceNow Otto for Vault application page on the ServiceNow Store, select **Buy**.
2. After approval has been granted, on your instance, navigate to **All > System Applications > All Available Applications > All**.
3. Using the search bar, search for the ServiceNow Otto for Vault application (sn_vault_gen_ai).
4. Select **Install**.
5. Verify that the ServiceNow Otto for Vault skills are active:
   a. Navigate to **All >Admin > AI Admin Hub > AI Skills**.
   b. In the workflow list, select **Vault**.
   c. Verify that the skills are active.

6. **Optional:** Verify that ServiceNow Otto for Vault agentic workflows are activated by following the steps in Activate an agentic workflow template.
   By default, the workflows are active when you install ServiceNow Otto for Vault. This step is in case a user deactivated them after installation.

Use guided setup for ServiceNow Vault

Use guided setup to configure an application with ServiceNow Vault.

Before you begin

Role required: Elevate to sn_vault_console.vault_console_admin role.

To secure custom apps, install the ServiceNow Otto for Vault application and make sure that all ServiceNow Otto for Vault skills and workflows are enabled. See Install ServiceNow Otto for Vault for more information.

Procedure

1. Navigate to **All** > **Vault** > **Vault console**.
2. In the Guided vault section, select **Get started** for your application within the **ServiceNow apps** tab.
   To begin the guided setup for your custom applications, go to the **Custom apps** tab. Select the **+ Add custom app** button, choose the app that you want to secure from the drop-down list, and then select **Get started**. Or you can use Ask Now Assist to secure your custom

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

applications through conversational prompts. For example, select **Ask Now Assist**. In the Now Assist panel, start the conversation with `Find and secure my custom apps`. See ServiceNow Otto panel for more information.

3. In **Select app data**, use the table to select the application data to be used with ServiceNow Vault and select **Review selection** when finished.

Select app data table fields

Label	Description
Table	The table the data is located in.
Column	The column the data is located in.
Existing Class	The current classification of the data.
Class to add	The proposed classification for the data.
Reason	The primary reason for the proposed class to add.

The proposed classes are based on table column names and application context.

4. In **Preview data classification**, review your data classification settings.

Preview data classification table fields

Label	Description
Table	The table the data is located in.
Column name	The column the data is located in.
Final class	The class the data will be assigned.

When finished, select the **Agree** check box and select **Classify data**.

5. In **Classification summary**, review the results of the data classification and select **Next** when finished.

Trouble?
Use Data Classification to review any data that failed to classify.

6. In **Protect existing data**, review the protection policies of the data.

Protect existing data table fields

Label	Description
Table	The table the data is located in.
Column	The column the data is located in.
Anonymization	Reports if a data anonymization policy can be, or already is applied to the data.
Field encryption	Reports if a field encryption policy can be, or already is applied to the data.
Zero trust access	Reports if a zero trust access policy can be, or already is applied to the data.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

7. **Optional:** Begin applying that column's respective application data protection policy by selecting **Available**.
   Review Vault tools and metrics for more information.
8. In **Protect real-time data**, review your real-time data protection policies.

Protect real-time data fields

Label	Description
Name	The name of the channel or column of a table.
Type	Indicates whether the data is from a channel or column.
Real-time anonymization	Reports if there is a real-time anonymization policy available, or already applied to the data.

Note: Real-time data is protected across the entire instance and all applications.

Select **Done** when finished.

Result

The selected application now has classified data and protection policies. It also reports relevant metrics to the ServiceNow Vault console dashboard.

Use agentic AI in ServiceNow Otto for Vault

Use the ServiceNow Otto for Vault agentic workflows to complete tasks autonomously.

Note: Depending on your license, you will have access to certain application features, generative AI skills, agentic workflows, and AI agents. For more information, see ServiceNow product tiers.

Available agentic workflows for ServiceNow Otto for Vault AI agent collection

Agentic workflow name	Description	Available AI agents
Securing custom apps with Vault agents	Proposes data classifications and available protections for a custom application.	Custom app recommendations
Access observer configuration	Views, creates, deactivates, and deletes Access Observer settings for a particular field.	Access observer configuration manager
Summarize access observer logs	Reviews and summarizes access logs for a specific field, identifying access sources, users, and their roles.	Access observer log analyzer
Field encryption with Vault module	Encrypts specific fields and configure secure access to users with designated roles.	Vault crypto module manager
Field Encryption and Auto Generate Access Policies	Encrypts a table field and creates a module access policy for each role that needs access to the field.	Field access auditor, Vault crypto module manager

© 2026 ServiceNow, Inc. All rights reserved.

Available agentic workflows for ServiceNow Otto for Vault AI agent collection (continued)

Agentic workflow name	Description	Available AI agents
Classifying ServiceNow assets with Vault agents	Recommends a data class for each ServiceNow column collected into the Data Catalog.	Classify assets with ServiceNow Vault

For a list of all ServiceNow Vault AI agents, see ServiceNow Vault AI agents.

Important: Some generative AI skills, AI agents, and agentic workflows are turned on by default. For more information, see AI agents, skills, and agentic workflows on by default.

AI model providers

You can use Now LLM Service, Azure OpenAI, Google Gemini or Anthropic Claude on AWS as the AI model provider for all generative AI skills and AI agents. Use the Configuration Controls in AI Control Tower to define which options are available, then set the skill-level preferences in the AI Admin Hub console. For more information, see Large language models on the ServiceNow AI Platform.

Agentic workflows and AI agents use the large language model configured for your instance. Unlike ServiceNow Otto for Vault skills, they don't define a default model of their own. If you change the model for your instance, the agentic workflows use the new model.

Turn off an agentic workflow or an AI agent

Agentic workflows and AI agents aren't listed with the ServiceNow Otto for Vault skills and can't be turned on or off from the skill list. To turn one off, use AI Agent Studio, or create a policy in AI Control Tower that prevents it from running.

Security

Enable security settings to run AI agents and agentic workflows using access control lists (ACLs) and user identities. You can configure and manage the ACLs in AI Agent Studio. See Implement access control in AI agents for more information.

Installed agents

There might be AI agents installed on your instance that are not used in agentic workflows. To learn how to see all agents that are available to you, see Find AI agents.

Securing custom apps with the Vault agents agentic workflow

Use the securing custom apps with Vault agents agentic workflow to get recommended data classifications and available protections for a custom application.

Securing custom apps with Vault agents agentic workflow overview

When you install ServiceNow Otto for Vault, this agentic workflow is turned on by default.

To modify the agentic workflow, duplicate it, and adjust the settings according to your requirements.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Secure custom apps

Get data classification and data protection recommendations for a custom application. The workflow requires that you have the sn_vault_console.vault_console_admin role and elevate to it.

To access and configure the agentic workflow:

1. Navigate to **All** > **AI Agent Studio** > **Create and manage**.
2. Select **Securing custom apps with Vault agents**.

Note: The securing custom apps with Vault agents agentic workflow is triggered automatically when you secure custom applications using ServiceNow Vault console dashboard. You can also invoke the agentic workflow manually in the ServiceNow Otto panel.

AI agents used in the securing custom apps with Vault agents agentic workflow

AI agents names and descriptions

Name	Description
Custom app recommendations agent	Uses various tools to perform the following: • Analyzes the table schema and its metadata. • Uses the recommend column classifications skill to propose classifications for the data in the table. • Proposes available field encryption protection. • Proposes zero trust access and data privacy protection.

There might be AI agents installed on your instance that are not used in agentic workflows. To learn how to see all agents that are available to you, see Find AI agents.

Access Observer configuration agentic workflow

Use the Access Observer configuration agentic workflow to view, create, deactivate, and delete Access Observer settings for a particular field.

Access Observer configuration agentic workflow overview

Access Observer helps you monitor the people and processes that access data on your instance. Use the Access Observer configuration agentic workflow to modify Access Observer settings to track access across your enterprise.

When you install ServiceNow Otto for Vault, this agentic workflow is turned on by default.

To modify the agentic workflow, duplicate it, and adjust the settings according to your requirements.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Configure Access Observer

Configure Access Observer settings to track data access. The workflow requires the following roles:

- sn_vault_console.vault_console_admin
- security_admin

Elevate to the roles that appear in the Elevate role list by selecting your profile icon and then selecting **Elevate role**.

Note: The `security_admin` role isn't included in the `sn_vault_console.vault_console_admin` role composition and doesn't appear in the Elevate role list. A user with the admin role must assign it through the standard user-administration process. If the workflow reports that you don't have the `security_admin` role, or that the role isn't active for your session, contact your admin. For more information, see ServiceNow Vault roles.

To access and configure the agentic workflow:

1. Navigate to **All** > **AI Agent Studio** > **Create and manage**.
2. Select **Access Observer configuration**.

Note: The Access Observer configuration agentic workflow is triggered automatically when you secure custom applications using ServiceNow Vault console dashboard. You can also invoke the agentic workflow manually in the ServiceNow Otto panel.

AI agents used in the Access Observer configuration agentic workflow

AI agents names and descriptions

Name	Description
Access Observer configuration manager agent	Uses various tools to view, create, deactivate, and delete Access Observer settings for a particular field.

There might be AI agents installed on your instance that are not used in agentic workflows. To learn how to see all agents that are available to you, see Find AI agents.

Summarize Access Observer logs agentic workflow

Use the summarize Access Observer logs agentic workflow to review and summarize access logs for a specific field, identifying access sources, users, and their roles.

Summarize Access Observer logs agentic workflow overview

Generate a summary of the user, role, and caller types that attempted to access a table column configured in Access Observer. For example, ask the agentic workflow to summarize access logs to view users who accessed a field, along with their roles and how they accessed the data.

When you install ServiceNow Otto for Vault, this agentic workflow is turned on by default.

To modify the agentic workflow, duplicate it, and adjust the settings according to your requirements.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Summarize Access Observer logs

Generate a summary of all Access Observer logs. The workflow requires the following roles:

- sn_vault_console.vault_console_admin
- security_admin

Elevate to the roles that appear in the Elevate role list by selecting your profile icon and then selecting **Elevate role**.

Note: The `security_admin` role isn't included in the `sn_vault_console.vault_console_admin` role composition and doesn't appear in the Elevate role list. A user with the admin role must assign it through the standard user-administration process. If the workflow reports that you don't have the `security_admin` role, or that the role isn't active for your session, contact your admin. For more information, see ServiceNow Vault roles.

To access and configure the agentic workflow:

1. Navigate to **All** > **AI Agent Studio** > **Create and manage**.
2. Select **Summarize Access Observer logs**.

Note: The summarize Access Observer logs agentic workflow is triggered automatically when you secure custom applications using ServiceNow Vault console dashboard. You can also invoke the agentic workflow manually in the ServiceNow Otto panel.

AI agents used in the summarize Access Observer logs agentic workflow

AI agents names and descriptions

Name	Description
Access Observer log analyzer agent	Uses various tools to generate a summary of the user, role, and caller types that attempted to access a table column configured in Access Observer.

There might be AI agents installed on your instance that are not used in agentic workflows. To learn how to see all agents that are available to you, see Find AI agents.

Field encryption with Vault module agentic workflow

Use the field encryption with Vault module agentic workflow to encrypt specific fields and configure secure access to users with designated roles.

Field encryption with Vault module agentic workflow overview

Add field encryption protection and improve your security posture with the field encryption with Vault module agentic workflow.

When you install ServiceNow Otto for Vault, this agentic workflow is turned on by default.

To modify the agentic workflow, duplicate it, and adjust the settings according to your requirements.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note: To encrypt a field and create its module access policies in the same conversation, use the field encryption and auto-generate access policies agentic workflow. See Field encryption and auto-generate access policies agentic workflow.

Use the field encryption with Vault module

Encrypt specific fields and configure user access. The workflow requires the following roles:

- sn_vault_console.vault_console_admin
- security_admin
- sn_kmf.admin
- sn_kmf.cryptographic_manager

Elevate to the roles that appear in the Elevate role list by selecting your profile icon and then selecting **Elevate role**.

Note: The `security_admin` role isn't included in the `sn_vault_console.vault_console_admin` role composition and doesn't appear in the Elevate role list. A user with the admin role must assign it through the standard user-administration process. If the workflow reports that you don't have the `security_admin` role, or that the role isn't active for your session, contact your admin. For more information, see ServiceNow Vault roles.

To access and configure the agentic workflow:

1. Navigate to **All** > **AI Agent Studio** > **Create and manage**.
2. Select **Field Encryption with Vault module**.

Note: The field encryption with Vault module agentic workflow is triggered automatically when you secure custom applications using ServiceNow Vault console dashboard. You can also invoke the agentic workflow manually in the ServiceNow Otto panel.

AI agents used in the field encryption with Vault module agentic workflow

AI agents names and descriptions

Name	Description
Vault crypto module manager agent	Uses various tools to encrypt fields and ensures that only those users with particular roles have access to those fields.

There might be AI agents installed on your instance that are not used in agentic workflows. To learn how to see all agents that are available to you, see Find AI agents.

Field encryption and auto-generate access policies agentic workflow

The field encryption and auto-generate access policies agentic workflow encrypts a table field and creates the access policies that its roles need.

Note: Depending on your license, you will have access to certain application features, generative AI skills, agentic workflows, and AI agents. For more information, see ServiceNow product tiers.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field encryption and auto-generate access policies agentic workflow overview

After you encrypt a field, only the roles that have access to the encryption module can read the data. Identifying those roles manually means reviewing access control lists (ACLs), or configuring Access Observer, waiting for the logs, and building the role list from the results. If a role is missing from the list, users lose access to the data and you must add that role afterward.

This agentic workflow retrieves the roles that can read the field. You refine the list, and then the workflow creates a module access policy for each role in the final list and encrypts the field.

When you install ServiceNow Otto for Vault, this agentic workflow is turned on by default.

To modify the agentic workflow, duplicate it, and adjust the settings according to your requirements.

Use the field encryption and auto-generate access policies workflow

Encrypt a field and create the module access policies for it. The workflow requires the following roles:

- sn_vault_console.vault_console_admin
- security_admin
- sn_kmf.admin
- sn_kmf.cryptographic_manager

Select your profile icon, select **Elevate role**, and then elevate to the roles that appear in the list.

Note: The `security_admin` role isn't included in the `sn_vault_console.vault_console_admin` role composition and doesn't appear in the Elevate role list. A user with the admin role must assign it through the standard user-administration process. If the workflow reports that you don't have the `security_admin` role, or that the role isn't active for your session, contact your admin. For more information, see ServiceNow Vault roles.

To access and configure the agentic workflow:

1. Navigate to **All** > **AI Agent Studio** > **Create and manage**.
2. Select **Field Encryption and Auto Generate Access Policies**.

Note: To invoke the agentic workflow, open the ServiceNow Otto panel and select **Field Encryption and Auto Generate Access Policies**. The workflow asks you to confirm each action before it runs. Nothing is encrypted and no policy is created until you confirm.

Important:

Elevated roles aren't evaluated when the workflow retrieves the roles that have access to the field. Grant access to elevated roles separately. The workflow states this once in each conversation.

The workflow encrypts the field with the `vault_encryption_module` encryption module and creates the module access policies against the same module.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

AI agents used in the field encryption and auto-generate access policies agentic workflow

AI agent names and descriptions

Name	Description
Field access auditor agent	Evaluates the table and field, retrieves the non-elevated user roles that have access to the field, applies the changes that you make to the role list, and returns the final list of roles.
Vault crypto module manager agent	Uses various tools to encrypt fields so that only users with particular roles have access to those fields.

There might be AI agents installed on your instance that are not used in agentic workflows. To learn how to see all agents that are available to you, see Find AI agents.

Classifying ServiceNow assets with Vault agents agentic workflow

The Classify assets with ServiceNow Vault agent recommends a data class for each ServiceNow column in the Data Catalog.

Note: Depending on your license, you will have access to certain application features, generative AI skills, agentic workflows, and AI agents. For more information, see ServiceNow product tiers.

Data class recommendations for ServiceNow assets

Data classification gives you visibility into the types of data hosted on your instance and supports compliance with privacy laws and industry regulations. Classifying columns manually is inconsistent between reviewers and doesn't scale to customer estates of many thousands of tables. Use this agentic workflow to recommend a data class for each column in scope, with a reason for each recommendation.

When you install ServiceNow Otto for Vault on an instance that has the ServiceNow Data Catalog Governance (Scope: sn_dcg_app) application, this agentic workflow is turned on by default.

To modify the agentic workflow, duplicate it, and adjust the settings according to your requirements.

ServiceNow assets and enterprise assets

The Data Catalog in Workflow Data Fabric collects table and column definitions from connected data sources and stores them as data assets. Definitions collected from a ServiceNow source come from the Dictionary Entries [sys_dictionary] table, which defines every table and field in the system. For more information, see ServiceNow metadata collector.

Data assets are grouped by origin. Assets collected from a ServiceNow source are ServiceNow assets, and assets collected from any other source are enterprise assets. This agentic workflow classifies ServiceNow assets only.

Recommendations are based on schema metadata: the table name and label, the column name and label, the dictionary entry, any existing classifications, and the name and description of the application that owns the table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The workflow recommends from the data classes already defined on your instance rather than from a fixed set, so recommendations reflect your own classification model.

Classify ServiceNow assets

Recommend and apply data classes for the ServiceNow columns in the Data Catalog. Role required: dcg_data_privacy_admin

To access and configure the agentic workflow:

1. Navigate to **All** > **AI Agent Studio** > **Create and manage**.
2. Select **Classify assets with ServiceNow Vault**.

Note: You can invoke this agentic workflow using one of the following methods:

- In the ServiceNow Otto panel, enter a prompt such as `Classify my ServiceNow assets` or `Recommend data classes for columns in the Data Catalog`.
- In the Workflow Data Fabric panel, select this agentic workflow from the available options.

For the procedure, see Classify ServiceNow assets.

AI agents used in the classifying ServiceNow assets with Vault agents agentic workflow

AI agents names and descriptions

Name	Description
Classify assets with ServiceNow Vault	Uses various tools to retrieve ServiceNow assets from the Data Catalog, recommend a data class for each column, and apply the recommendations that you confirm.

There might be AI agents installed on your instance that are not used in agentic workflows. To learn how to see all agents that are available to you, see Find AI agents.

Classify ServiceNow assets

Run the Classify assets with ServiceNow Vault agent to get a recommended data class for each ServiceNow column in the Data Catalog, review the recommendations, and apply them.

Before you begin

The following applications must be installed:

- ServiceNow Data Catalog Governance (sn_dcg_app)
- ServiceNow Otto for Vault version 3.1 or later

Role required: dcg_data_privacy_admin

About this task

The agent provides AI recommendations for the user to review before applying them. Recommendations are saved only after the user confirms.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Open the ServiceNow Otto panel.

   You can start the agent from the platform ServiceNow Otto panel or from the Workflow Data Fabric panel. The agent is offered as a selectable option in the Workflow Data Fabric panel only.

2. Select **Classify assets with ServiceNow Vault**.

   In the platform ServiceNow Otto panel, the agent isn't offered as an option. Enter a prompt such as `Classify my ServiceNow assets` or `Recommend data classes for columns in the Data Catalog`. Both methods start the same agent.

3. Select the category of assets to classify:
   - **Unclassified assets** — classify only the assets that have no data class.
   - **Classified assets** — generate new recommendations for the assets that already have a data class. Existing classifications aren't replaced.
   - **All assets** — classify every asset available to you.

   The agent starts generating recommendations in the background.

   Trouble?

   If the agent reports that no assets were found, verify that the metadata collector has run for the ServiceNow source. Verify that assets exist in the category you selected.

4. In the conversation, select the **Data sensitivity classification** link.

   The results open in a panel beside the conversation.

5. Select **Refresh** to update the progress tracker and the results.

   Results appear as recommendation pages are generated. The progress tracker reports one of the states in the following table.

   Recommendation states

State	Description
In progress	Some pages are still being generated. Refresh to check for more results.
Complete	All pages are generated. The recommendations are ready to review.
Complete with some columns skipped	Recommendations couldn't be generated for some assets because of large language model processing errors. Review the available results and confirm to apply them. Only the generated recommendations are saved.

6. Review the recommendations.

   Each row shows the table, the column, the recommended data class, and the reason for the recommendation. Scroll the results horizontally to see all columns.

   To narrow the results, filter by data class, sort by a column, or search by table or column name.

7. When the agent asks whether to apply the recommended classifications, confirm or decline.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Description
Confirm	The agent saves the recommended classifi cations in the background. Confirm only af ter all recommendations are generated. If rec ommendations are still being generated, the agent asks you to wait and then asks again.
Decline	The agent asks you to confirm the cancella tion. Select **Yes, cancel** to cancel the run, or **No, go back** to return to the apply question.

Warning:

If no recommendations could be generated, the agent tells you that there's nothing to save and ends the run when you confirm. When you decline, processing doesn't stop immediately because the agent first finishes the work already in progress. This might take a minute or two. None of the recommendations from this run are applied.

Result

The agent saves the recommended classifications to the ServiceNow classification tables in the background. The classifications appear on the corresponding data assets in the Data Catalog after the next ServiceNow metadata collector run.

Note:

If a recommended data class is already recorded against a column, no duplicate entry is created. If the recommended data class differs from an existing one, the recommended class is added and the existing class is retained.

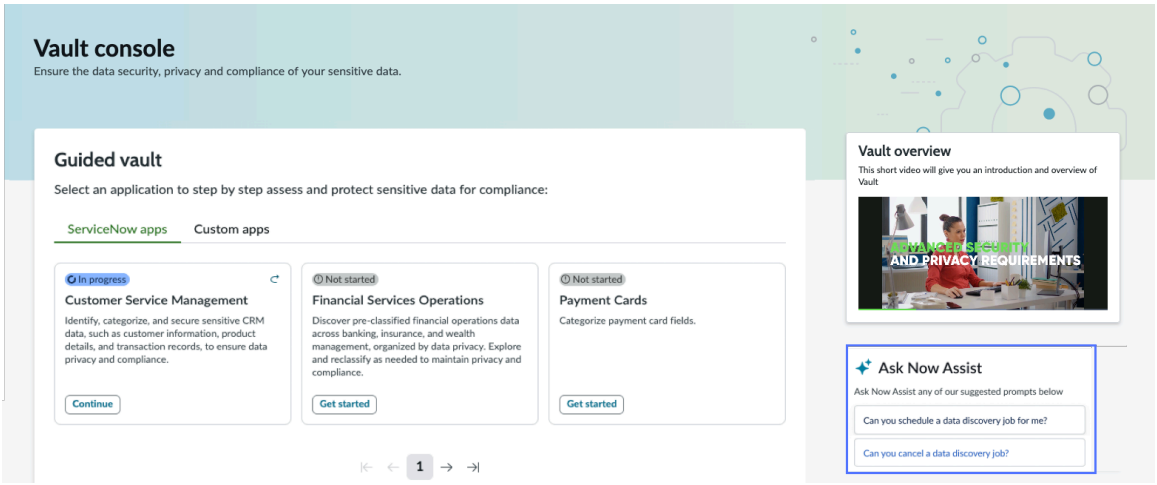
To check the applied classifications after the collector runs, see View data asset details.

Trouble?

If the run completes with some columns skipped, check the system logs for the cause of the processing errors. Run the agent again for the skipped assets.

Related topics

- Explore data assets in Data catalog
- Run metadata collectors
- Assign roles to Data catalog users



Use generative AI skills in ServiceNow Otto for Vault

The ServiceNow Otto for Vault application includes the generative AI skills and features that enable you to streamline your administrative workload.

Note: Depending on your license, you will have access to certain application features, generative AI skills, agentic workflows, and AI agents. For more information, see ServiceNow product tiers.

After you activate skills, they appear in the ServiceNow Otto panel in ServiceNow Vault console.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

By default, all skills exist in the global domain. When you use AI in a domain-separated environment, users are only able to access data in their domain. For example, if a user uses the summarization skill, AI only uses material that exists in the user's domain when generating that summary. Additionally, there is no co-mingling of data for domain-separated instances when using generative AI skills. The data resides only on the instance, and the shared services used for generative AI do not persist any requests (prompts) and responses. For more information, see Domain separation in the AI Admin Hub console. (Note that global domain is not the same as global scope. For more information, see Exploring Next Experience pickers.)

Generate a custom data pattern by using ServiceNow Otto for Vault

Use the generate custom data pattern skill to create a custom regular expression data pattern from your description and add it as an active data pattern to your instance.

Before you begin

- Install ServiceNow Vault. For more information, see Configuring ServiceNow Vault.
- Ensure that the generate custom data pattern skill is active. For more information, see Activate an AI skill.

Role required: sn_vault_console.vault_console_admin

About this task

This skill improves your efficiency by reducing the time required to understand and write regular expressions.

Procedure

1. Navigate to **All** > **Vault** > **Vault console**.
2. In the ServiceNow Otto panel, select **Generate custom data pattern** and specify the details.

Example

Example prompt: `I need help creating a regex to detect sensitive data for a Netherlands drivers license.`

Check role access for an encrypted column with ServiceNow Otto for Vault

Use the check role access for encrypted column skill to identify user roles that have access to encryption and decryption keys in your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

- Install ServiceNow Vault. For more information, see Configuring ServiceNow Vault.
- Ensure that the check role access for encrypted column skill is active. For more information, see Activate an AI skill.

Roles required: sn_vault_console.vault_console_admin and security_admin

Note: The `security_admin` role isn't included in the `sn_vault_console.vault_console_admin` role composition and doesn't appear in the Elevate role list. A user with the admin role must assign it through the standard user-administration process. If the skill reports that you don't have the `security_admin` role, or that the role isn't active for your session, contact your admin. For more information, see ServiceNow Vault roles.

Procedure

1. Navigate to **All** > **Vault** > **Vault console**.
2. In the ServiceNow Otto panel, select **Check role access for encrypted column** and specify the details.

Example
Example prompt: `Which roles have decryption key access to an encrypted column? Access includes read access.`

Schedule a Data Discovery job with ServiceNow Otto for Vault

Use the schedule data discovery job skill to schedule one-time or recurring Data Discovery jobs with ServiceNow Otto for Vault. Data Discovery jobs can detect sensitive data such as PII or PHI provided as input to the Azure OpenAI model.

Before you begin

- Install ServiceNow Vault. For more information, see Configuring ServiceNow Vault.
- Ensure that the schedule Data Discovery job skill is active. For more information, see Activate an AI skill.

Role required: sn_vault_console.vault_console_admin

Procedure

1. Navigate to **All** > **Vault** > **Vault console**.
2. In the ServiceNow Otto panel, select **Schedule data discovery job** and specify the job details.

Example
Example prompt: `Configure a data discovery job that scans the tables Task and Knowledge, looking for data patterns like Credit Card-Visa and Phone Number in columns such as Description and Text. Schedule a sample scan to occur on August 15th, 2025, with a time window from 10:00 AM to 5:00 PM. Name the job "Credit Card & Phone Number Scan" and describe it as "Scans for credit card and phone number data in Task and Knowledge tables."`

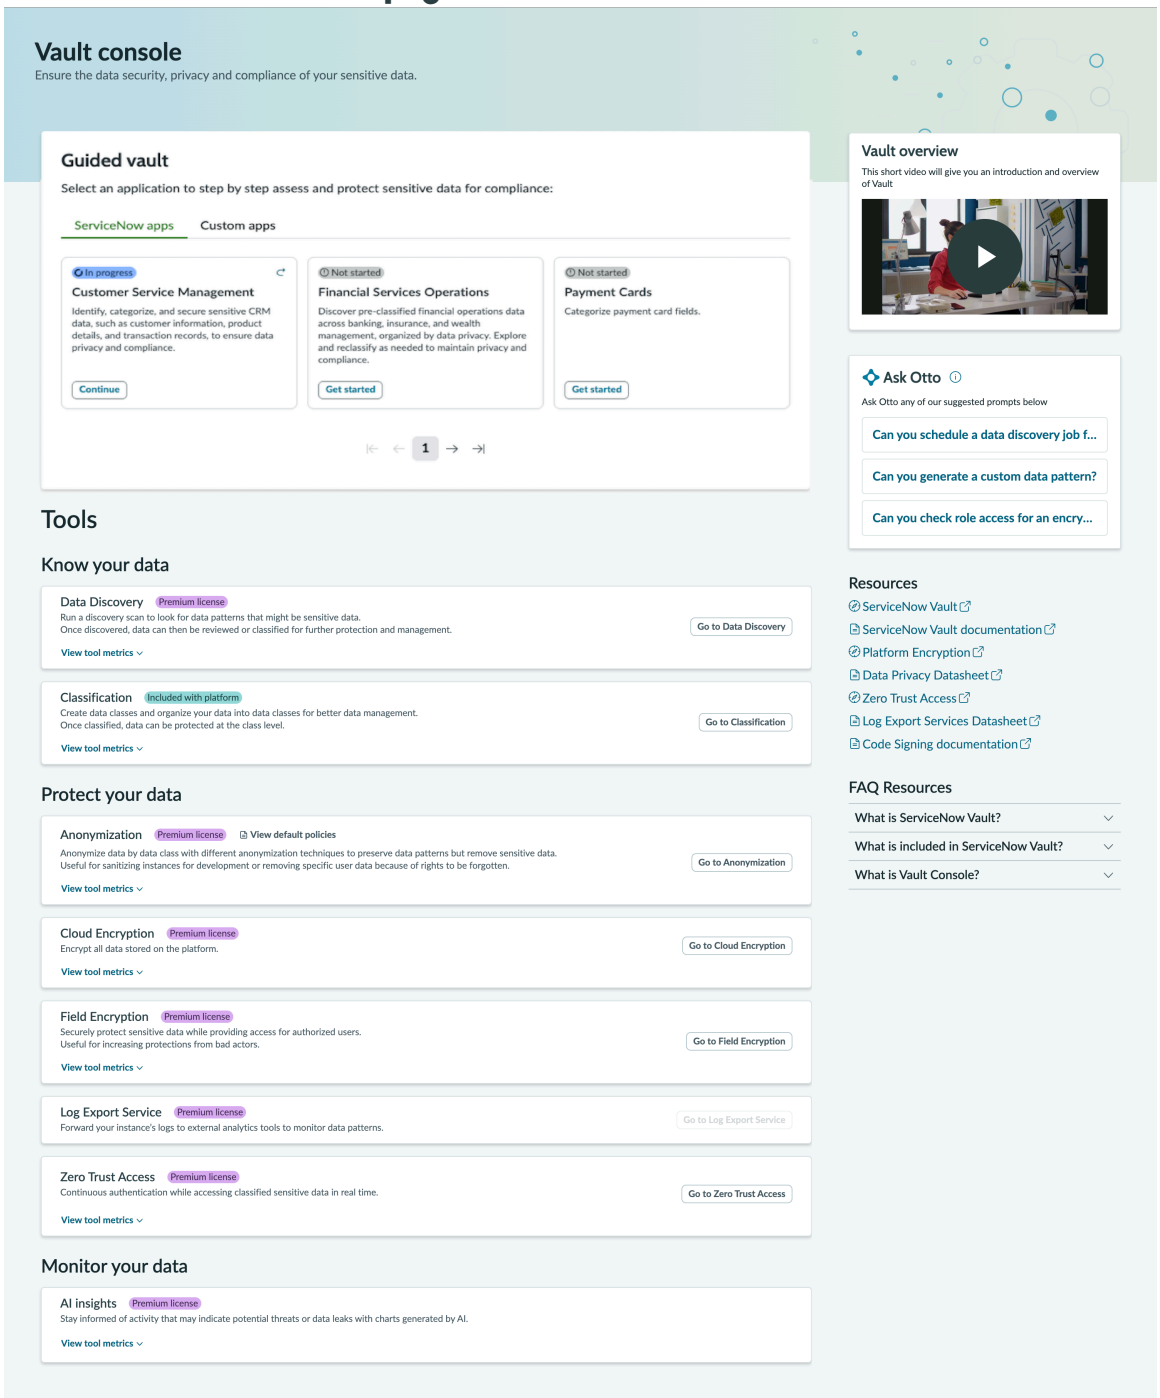
ServiceNow Vault console dashboard

Use the ServiceNow Vault console dashboard to track and manage your ServiceNow Vault security tools.

The dashboard provides an easy way to review the security, privacy, and compliance of your sensitive data. The dashboard reports on ServiceNow Vault tools and their various metrics, as well as showing guided setup for applications compatible for ServiceNow Vault.



To access the ServiceNow Vault console dashboard, navigate to **All** > **Vault** > **Vault Console**

Note:

If you open the dashboard without elevating to the `sn_vault_console.vault_console_admin` role, the dashboard is read-only. For more information, see ServiceNow Vault roles.

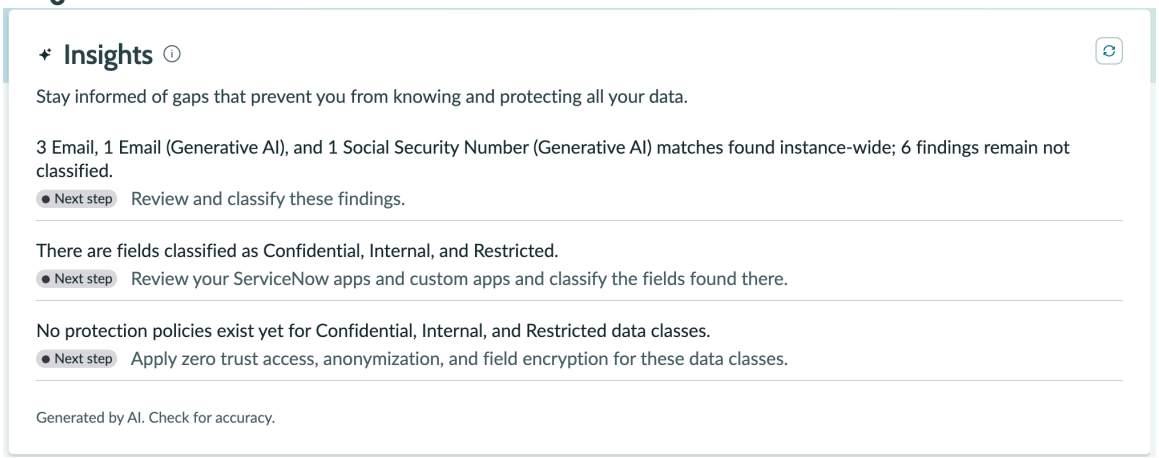
For more information, see Default policies and configurations in ServiceNow Vault.

Insights in ServiceNow Vault console

Insights uses AI to summarize the ServiceNow Vault console metrics and recommend a next step for each area of your data security.

The ServiceNow Vault console home page reports many separate metrics and charts. Insights reads those same metrics and states, in plain language, the current state of your data security and what you can do next. You don't have to interpret each chart to find the areas that need attention.



Insights appears at the top of the ServiceNow Vault console home page.

Note:

Insights and the charts draw on the same source data, so the two report the same values. Insights doesn't add information that the charts don't already report.

Insights section in ServiceNow Vault console

What each insight contains

Each area of your data security gets one insight and one next step:

Insight

A summary of the current state for that area. For example, which patterns data discovery found across your instance, or how many findings aren't classified yet.

Next step

A recommended action you can take to protect your data further. For example, reviewing and classifying new findings, or applying field encryption to unencrypted classified fields.

Insights are reported in this order:

1. Data discovery
2. Classification
3. Data protection, which combines Anonymization, Field Encryption, and Zero Trust Access into a single insight

When an insight isn't shown

An individual insight and its next step are left out when any of these conditions apply:

- There's no genuine next step for you to take in that area.
- The product for that area isn't installed on your instance, so no data is available for it.
- No graph data is returned for that product.

Retrieval runs separately for each product. If retrieval fails for one product but succeeds for others, the insight for the failed product is left out and the rest are still reported. No error message identifies the omitted product.

Refreshing insights

Select the refresh icon in the Insights section to generate the summary again from the latest data. A loading state appears while generation is in progress.

Reloading the whole page retrieves the latest data as well. Refreshing the section is useful when you've had the home page open for some time without reloading it.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Availability and error states

Insights requires the ServiceNow Otto for Vault application. When ServiceNow Otto for Vault isn't active on your instance, the Insights section is hidden.

Insights also requires the Generative AI Controller license, which is included with ServiceNow Otto for Vault.

When the summary can't be generated, the section reports `Unable to generate insights. Please try again later.` Select the refresh icon to try again.

Insights carries the text "Generated by AI. Check for accuracy". Review the recommended next steps before you act on them.

Note: Depending on your license, you will have access to certain application features, generative AI skills, agentic workflows, and AI agents. For more information, see ServiceNow product tiers.

Role requirements

Insights is visible only to users with the `sn_vault_console.vault_console_admin` role. Elevate to this role to view Insights. Insights is hidden for users with the `sn_vault_console.vault_console_auditor` role. For more information about elevating roles, see ServiceNow Vault roles.

Vault tools and metrics

Learn about the tools and metrics ServiceNow Vault uses to protect and discover sensitive data.

ServiceNow Vault integrates with several tools to provide you with a cohesive overview of your sensitive data security. You can hover over a widget to get further insight on the reported data. Select the **Go to** button on any tool to go to its respective page.

Know your data

ServiceNow Vault uses Data Discovery and Data Classification help you understand and know your data.

Tools and metrics

Tool	Metric	Description
Discovery Use Data Discovery to run a discovery scan to look for data patterns that might be sensitive data. Once discovered, data can then be reviewed or classified for further protection and management.	Discovered data	Occurrences of sensitive data across tables in your instance, categorized by sensitive data pattern type.
	Discovery status	Current state of all discovered sensitive data patterns, including new findings pending review, classified, or marked as ignored.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Tools and metrics (continued)

Tool	Metric	Description
	Discovered attachments	Total sensitive data occurrences in attachments across tables in your instance.
Classification Data Classification creates data classes and helps organize your data into data classes for better management. Classified data can be protected at the class level.	Classifiable data	Tables or columns that can be classified.
	Classified data	Dictionary entries, tables, or columns that are classified.

Protect your data

ServiceNow Vault uses data anonymization, cloud encryption, field encryption, log export, zero trust access, and code signing to help secure and protect your data.

Tools and metrics

Tool	Metric	Description
Anonymization Anonymize data by data class with different anonymization techniques to preserve data patterns but remove sensitive data. Useful for sanitizing instances for development or removing specific user data because of rights to be forgotten. Default real-time protection policies are available from this card and are applied in addition to any existing policies. For more information, see Default policies and configurations in ServiceNow Vault.	Existing data	All classified data per workflow that is anonymized or not.
	Real time data	Number of successful real-time calls to anonymize sensitive data as it enters the platform, by channel.
	Anonymization run times	How long scheduled user- or data-based jobs ran in hours for existing data.
Cloud Encryption with Key Management Securely protect sensitive data in encrypted storage for your data using block encryption, along with enhanced key management.	Active cloud key	Total rotations of the active cloud key. **Note:** To view this data, you need the Key Management Framework admin role (sn_kmf.admin or sn_kmf.cryptographic_manager).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Tools and metrics (continued)

Tool	Metric	Description
	Key rotation	Time elapsed between each rotation of active keys on your instance. Bar height measures how long a key was used before rotation. **Note:** To view this data, you need the Key Management Framework admin role (sn_kmf.admin or sn_kmf.cryptographic_manager).
Field Encryption Securely protect sensitive data while providing access for authorized users. Useful for increasing protections from bad actors.	Encrypted fields classification status	Classification status of all data protected with Field Encryption.
	Classes protected with Field Encryption	The proportion of classified data protected withField Encryption.
	Active encryption keys	Number of active Field Encryption keys in your instance. Ideally, the number of active keys matches the number of classifications. **Note:** To view this data, you need the Key Management Framework admin role (sn_kmf.admin or sn_kmf.cryptographic_manager) and the security_admin role.
Exploring Log Export Service (LES) Forward your instance's logs to external analytics tools to monitor data patterns. New users can activate default configurations from this card. For more information, see Default policies and configurations in ServiceNow Vault.	Data exported in the past 6 months	Total volume of data, in MB, exported to external analytics tools each month over the past 6 months, excluding the current month. This trend shows how your monthly export volume changes over time.
	Most exported topics in the past 6 months	The topics with the most exported data, in MB, over the past 6 months, excluding the current month. Topics are ranked from highest to lowest export volume.
	Data exported this month by topic (MB)	Total volume of data, in MB, exported so far during the

Tools and metrics (continued)

Tool	Metric	Description
		current month, categorized by topic. This metric covers the current month, which the 6-month metrics exclude.
Zero Trust Access (ZTA) Continuous authentication while accessing classified sensitive data in real time. Default step-up authentication policies are available for Vault customers. For more information, see Default policies and configurations in ServiceNow Vault.	Continuous Authentication classification status	Number of classifications that are protected due to the Continuous Authentication policies.
	Classes protected with Continuous authentication	Number of classes protected with continuous authentication, categorized by class.
Code Signing Use digital signatures to verify the authenticity and integrity of your data and prevent unauthorized or tampered records from being processed. Select **Go to Code Signing** to open the Code Signing Health and Status Dashboard.	Operations applied on code-signed records in the past week	Code-signed records that were created, updated, or deleted in the past week on your production instance.
	Operations applied on code-signed records by table	Tables with the most code-signed records that were created, updated, or deleted.

Monitor your data

The AI Insights section within ServiceNow Vault helps you keep track of activities that may indicate potential threats or data leaks. These activities are generated from channels such as ServiceNow Otto and Virtual Agent, as well as database tables configured with real-time discovery. This insight can help you prioritize your data protection strategies more effectively. Select **View tool metrics** to see the underlying metrics.

AI Insights charts

Metric	Chart Component	Description
User entering sensitive data	In tables with real-time discovery	The number of users whose sensitive data entries were detected in database tables configured with real-time discovery.
	In channels	The number of users whose sensitive data entries were detected within channels such as ServiceNow Otto or Virtual Agent.
Channels with sensitive data	Channel bars (x-axis)	Stacked bars representing each channel where sensitive data was detected, broken down by data patterns. The data pattern legend displays the color code for each pattern. They may include driver license

AI Insights charts (continued)

Metric	Chart Component	Description
		numbers, financial information, and personal identifiers.
	Occurrences of sensitive data (y-axis)	The count of sensitive data instances detected per channel.
Tables with sensitive data found through real-time discovery	Table bars (x-axis)	Stacked bars representing each database table where sensitive data was detected, broken down by data patterns.
	Occurrences of sensitive data	The count of sensitive data instances detected per table.

All ServiceNow Vault tools

Encryption

Key Management and Field Encryption is a suite of highly configurable encryption modules

Code Signing

Help improve security by validating sensitive application configuration data and scripts before they are used.

Data Privacy

Use the Data Privacy plugin to remove personally identifiable information (PII) from user data when it is migrated from a production instance to a non-production instance.

Data Discovery

The Data Discovery plugin enables you to find personally identifiable information (PII) from user data. The data can then be classified for further security measures.

Log Export Service

Zero Trust Access

Improve security, performance, and user experience by importing ServiceNow log data into enterprise log analytics using the log export service.

ServiceNow Session Access enables organizations to dynamically reduce user privilege in a web session

Default policies and configurations in ServiceNow Vault

ServiceNow Vault has a set of ready-to-use policies and configurations for selected tools to help you get started quickly.

Note: Default policies and configurations are available only on instances with a ServiceNow Vault subscription.

Defaults help new users get started by providing a baseline of ready-to-use settings. The following tools support default policies and configurations:

- Anonymization
- Log Export Service
- Zero Trust Access

How defaults are applied

Default behavior differs by tool:

Anonymization

Default real-time protection policies are added to your instance when you have the Data Privacy plugin and the Vault Console store app installed. These defaults are applied in addition to any existing real-time protection policies. Select **Activate** on the tool card on the tools page to apply them.

Log Export Service

Default configurations are applied only when no existing Log Export Service configurations exist on your instance. If existing configurations are present, the existing setup applies and no defaults are created. Select **Activate** on the tool card to apply defaults, or **Go to Log Export Service** if configurations already exist.

Zero Trust Access

Default step-up authentication policies are created automatically when all of the following conditions are met:

- A ServiceNow Vault subscription is present on the instance.
- Both Vault Console and the Zero Trust - Continuous Authentication plugin (`com.snc.zero_trust_continuous_authentication`) are installed.
- No existing Zero Trust Access policies are present. If any policy already exists, the default policies aren't created.

The default policies protect the following Vault configuration tables: Cryptographic Module [sys_kmf_crypto_module], Encrypted Field Configuration [sys_platform_encryption_configuration], and Module Access Policy [sys_kmf_crypto_caller_policy].

When a user tries to access one of these tables, the policy requires re-authentication via MFA (multi-factor authentication) for local logins, or redirects SSO users to their identity provider. Maint users are excluded from policy evaluation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

To review the default policies, select **View default policies** on the Zero Trust Access tool card.

> **Note:** A user with the ca_admin role can deactivate or reactivate a default policy. To do so, navigate to **All** > **Continuous Authentication** > **Policies**, select the policy name to open its record, and then select **Deactivate** or **Activate**.

View default policies and configurations

Select **View default policies** or **View default configurations** on the tool card to review defaults. Selecting a policy or configuration name opens its management page.

Log Export Service version requirement

Default Log Export Service configurations require Log Export Service version 3.5.0 and later. On earlier versions, the **Activate** option isn't available and the tool card shows **Go to Log Export Service** instead.

AI limitations

This application uses artificial intelligence (AI) and machine learning, which are rapidly evolving fields of study that generate predictions based on patterns in data. As a result, this application may not always produce accurate, complete, or appropriate information. Furthermore, there is no guarantee that this application has been fully trained or tested for your use case. To mitigate these issues, it is your responsibility to test and evaluate your use of this application for accuracy, harm, and appropriateness for your use case, employ human oversight of output, and refrain from relying solely on AI-generated outputs for decision-making purposes. This is especially important if you choose to deploy this application in areas with consequential impacts such as healthcare, finance, legal, employment, security, or infrastructure. You agree to abide by ServiceNow's AI Acceptable Use Policy, which may be updated by ServiceNow.

Data processing

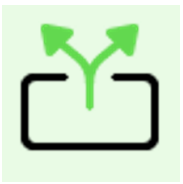
This application requires data to be transferred from ServiceNow customers' individual instances to a centralized ServiceNow environment, which may be located in a different data center region from the one where your instance is, and potentially to a third-party cloud provider, such as Microsoft Azure. This data is handled per ServiceNow's internal policies and procedures, including our policies available through our CORE Compliance Portal.

Data collection

ServiceNow collects and uses the inputs, outputs, and edits to outputs of this application to develop and improve ServiceNow technologies including ServiceNow models and AI products. Customers can opt out of future data collection at any time, as described in the AI Opt-Out page.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Platform Security

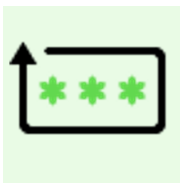


Platform security provides capabilities to secure the instance.

Security Center

Allow admins to continuously maintain the highest level of security posture and easily monitor for insecure events and behaviors.

Log Export Service



Log Export Service (LES) lets you seamlessly export your instance system and application logs into your enterprise security analytic tools. The service provides a highly scalable and near real-time integration with your analytic tools that is easy to setup and maintain.

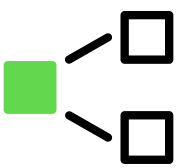
Logs

Logs module provides a variety of logs that you can use to troubleshoot and debug transactions and events that take place within the instance.

Secrets Management

Use ServiceNow Secrets Management for granular management of access to your passwords to fit your business needs.

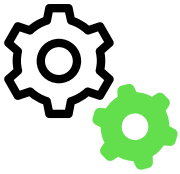
Code Signing



Code Signing creates digital signatures for the data which later are checked to confirm the authenticity and integrity of the data.

Antivirus Scanning Capabilities

Use Antivirus Scanning to help protect your instance against virus infections that can be introduced by file attachments to your system records, such as incidents, problems, and stories.



HTML Sanitizer

Auditing

High Security Settings

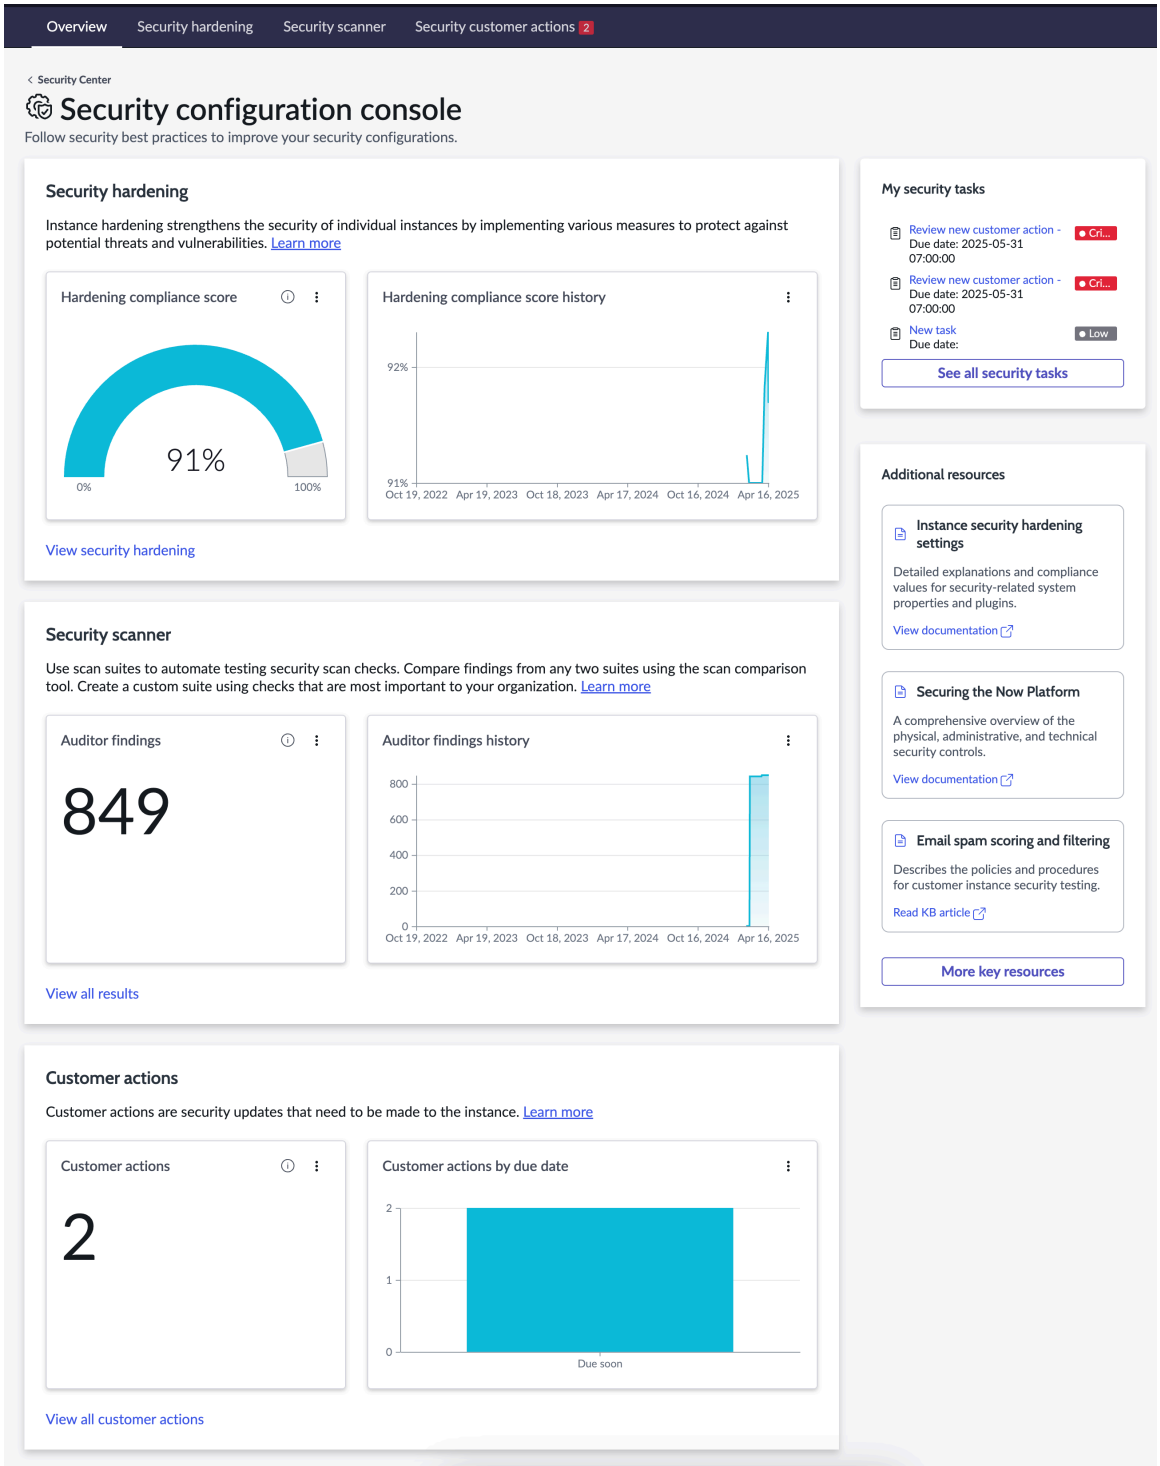
Machine identities are digital credentials such as certificates, keys, and tokens. Servers, applications, containers, and cloud services use these identities authenticate with each other. Use the **Machine Identity Console** to manage the machine identities used for integrations with ServiceNow.

Access Analyzer

Use the **Analyze Access and Permissions** console to view permissions for a selected user, role, group, or compare access between two users.

Scripting Governance for default group



Use the Scripting Governance Tool to configure preferences for the Conditional Script Writer group. Users in this group are assigned the *snc_required_script_writer_permission* role, which allows users to access scripts and script-like fields across the platform.

With the settings on this console you can turn auto-assignment of this role on or off, as well manually assign users to the group. You can also see information on who is assigned, and scan your instance to find users who have scripted in a specific time frame.

Security configuration console

Use the security configuration page to get an overview of the security posture of your instance. View your hardening compliance score, discover graphical trends, analyze the top non-compliant hardening settings, and see the results of your security scans.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Navigation bar

Use the bar at the top of the page to navigate between this page and the security hardening, security scanner, or security Customer Actions section of Security Center.

Security hardening

Find details about your hardening compliance in the security hardening section. Select the cards on in this section to navigate to the Security hardening page.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The hardening compliance score is a percentage that shows how closely your security settings align with the recommended settings. The security hardening section shows this percentage, as well as the history of the score on your instance over time.

Security scanner

Review the results of automated security scan checks using the security scanner section. These checks and help you find security vulnerabilities, inefficiencies, and issues with compliance.

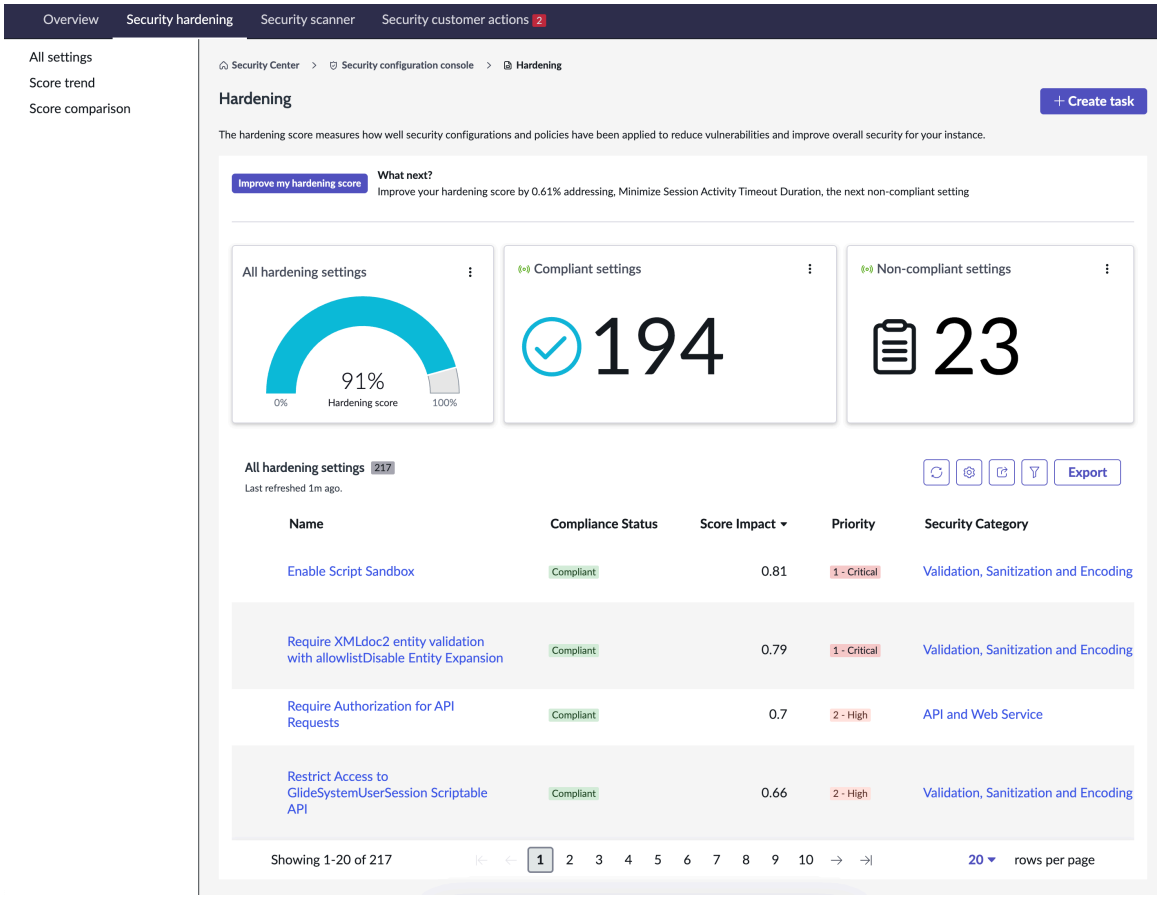
Select the cards on in this section to navigate to the security scanner page.

Customer actions

Find security updates that can be made to the instance in the Customer Actions section. This section shows the number of available actions and a chart indicating the due date for these actions. Select the cards on in this section to navigate to the Customer Actions page.

My Security Tasks

View the most urgent Security Tasks assigned to you. Select a task to view its details, or select **See all Security Tasks** to view a complete list of Security Tasks.



Additional resources

Use the additional resources section on the edge of the screen to navigate to documentation and videos relevant to learning Security Center as well as information on managing instance security.

Security hardening

View your hardening compliance score, compare it with previous scores, and change settings to improve your compliance score and security posture in the security hardening page.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Hardening settings specify recommended values for the security-related properties and plugins in the ServiceNow AI Platform. The hardening tool calculates the hardening setting compliance score as a percentage. This number indicates how compliant your instance is with the Security Center hardening settings.

The formula for calculating the hardening compliance score:

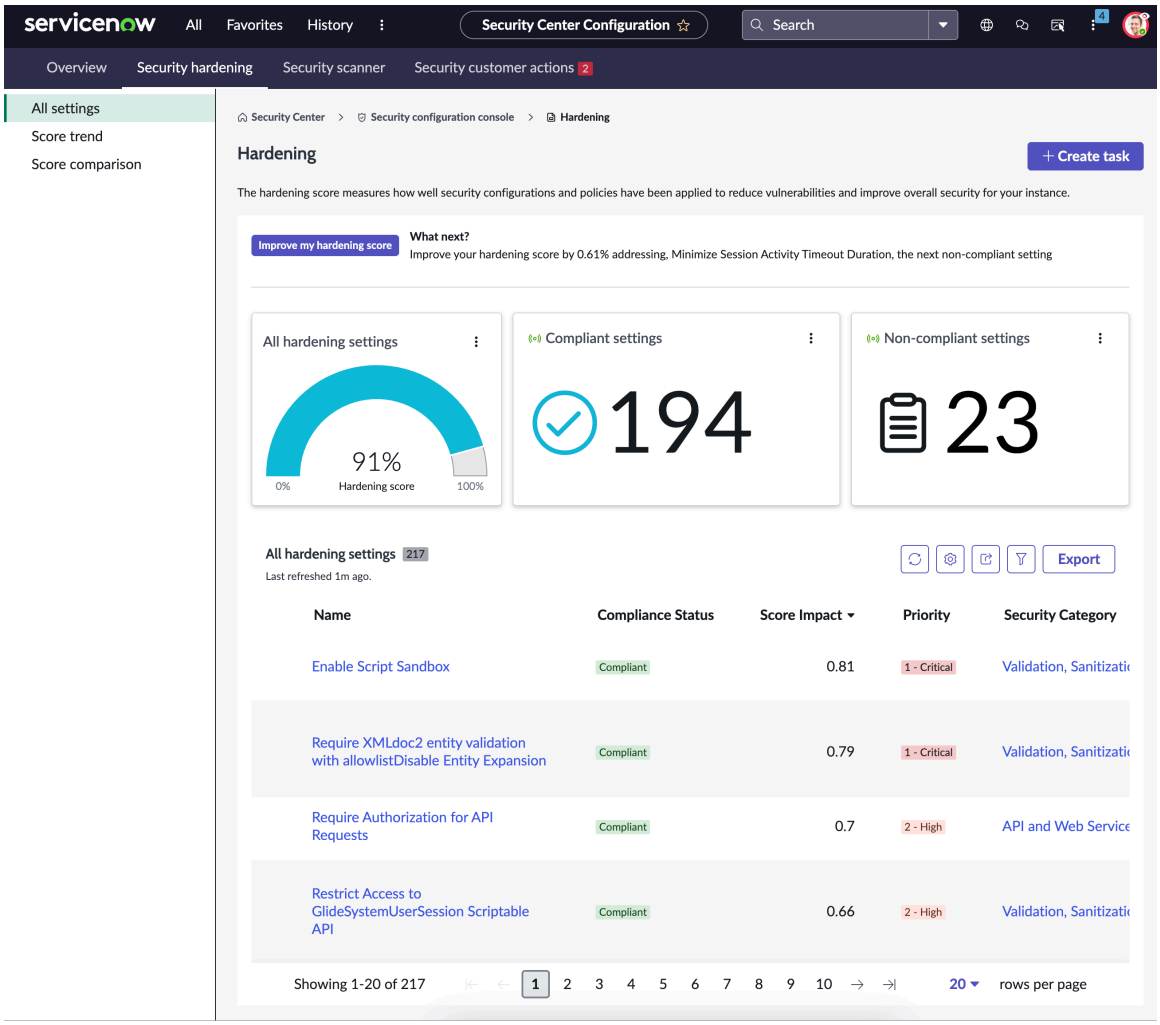
- Each hardening setting has a risk score between 0-10. You can see the values of individual settings in the **All settings** section.
- The score equals the sum of all the compliant risk scores divided by the sum of all risk scores.

For example, the sum of all the compliant risk scores is 25.4, and the total for all risk scores is 34.9. For this sum, the compliance score is (25.4 /34.9) × 100 which equals 72.7. This decimal gets rounded up to the nearest whole number and will therefore be equal to 73.

This calculation is automatically performed on the first of the month, or after an installation or reinstallation of ServiceNow Security Center. You can trigger a recalculation at any time using the **Update score** button on this page.

Security hardening subsections

The security hardening section contains three subsections that you can select on the left edge of the screen.



- All settings
- Hardening compliance score trend
- Hardening score comparison

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

All settings

Review all of your instance hardening settings available from a single page.

The **All Settings** page displays information about all instance hardening settings. Use the buttons in the upper right to refresh, filter, and export this information.\

Use the **+Create task** button to create a Security Task to complete a Customer Action. This button appears both in the **All Settings** page as well as the pages for individual hardening settings. For details, see Security Tasks.

The following information about hardening settings can be found on the list.

Name

Name of the hardening setting.

Compliance Status

Whether the setting is properly configured according to the system's recommendation (compliant) or must be configured (non-compliant)

Score Impact

Impact this hardening setting has on your security posture, expressed as a percentage. All score impacts sum to 100%.

Priority

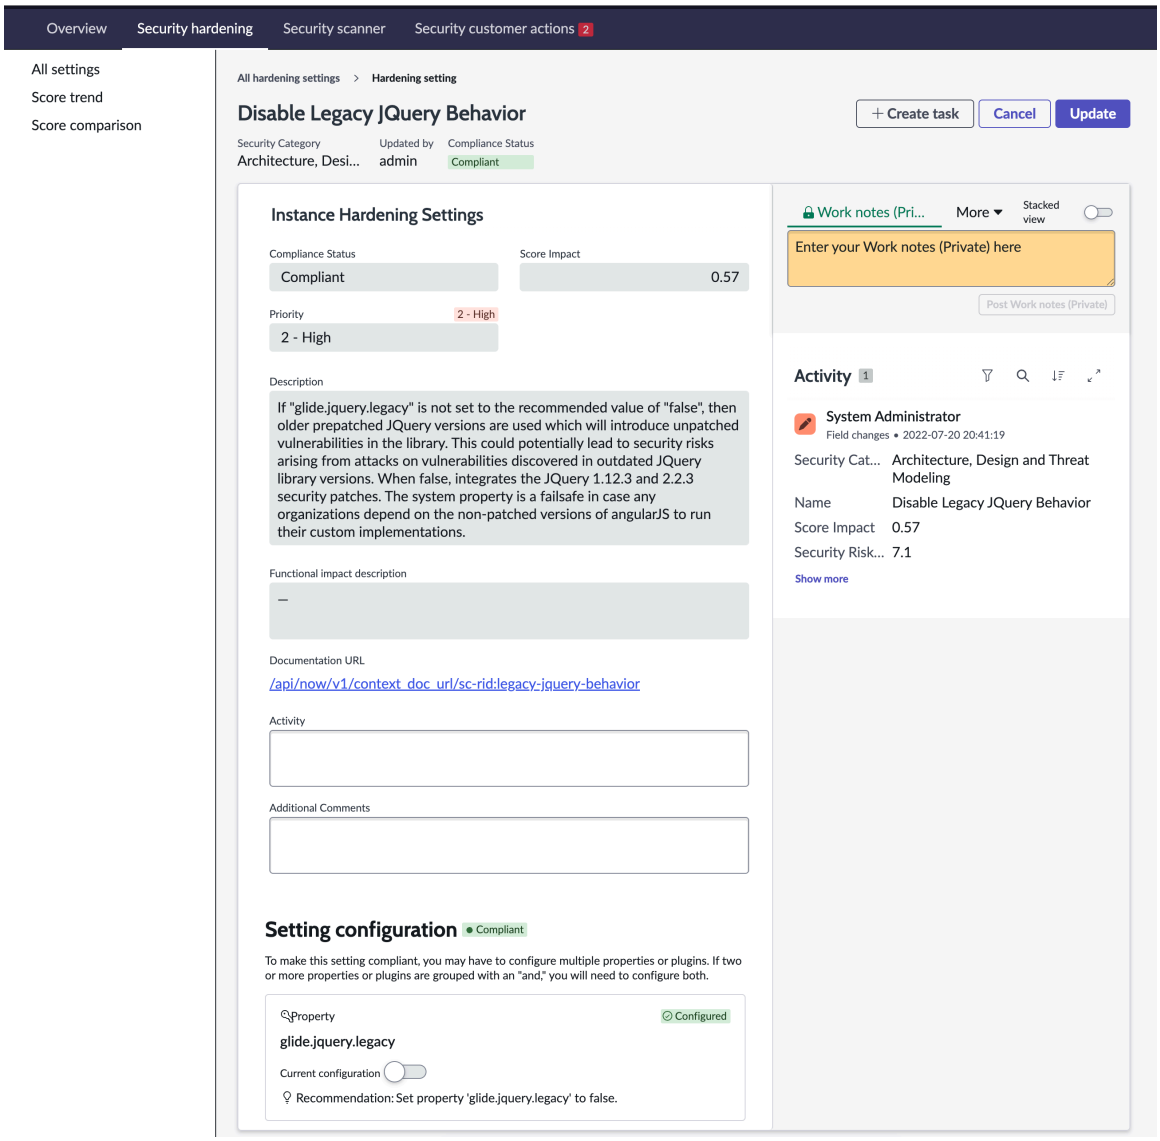
The criticality of the setting: Critical, High, Moderate, and Low. A higher score indicates a greater impact and priority.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Security category

The security category of the property. Select the category to view details.

Resolution Details



Description of the steps to remediate the security vulnerability of the hardening setting.

To learn how to configure a property hardening setting see Increase hardening compliance score.

Hardening settings details

Analyze the details of a hardening setting by selecting its link within the Security Center app.

Navigate to **Hardening** > **All settings**, and then select a hardening setting to be redirected to a page within the hardening setting tool that displays its security-related information.

Use the **+Create task** button to create a Security Task to complete a Customer Action. For details, see Security Tasks.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Hardening settings configuration details

Configuration attribute	Description
Compliance status	Indicates if the hardening setting is compliant nor not.
Score impact	A percentage that indicates how much this hardening setting impacts your security posture.
Priority	A number within the range of 1-4, with 1 having the most weight that indicates the strength of impact this hardening setting has on your security posture.
Functional impact	The impact this hardening setting has on the operation of your instance.
Description	A general overview about the hardening setting.
Documentation Url	Link to documentation for the hardening setting.
Activity	Notifications of updates related to the hardening setting.
Setting configuration	Details related to the compliance status of your hardening setting along with instructions on how to make them compliant. **Note:** Some hardening settings may require you to configure multiple properties and plugins to make them compliant.

Filter hardening settings

Simplify your hardening review process using filters. These filters can create a working list of hardening settings for review, which restored for later use and shared with other users.

Before you begin

Role required: admin

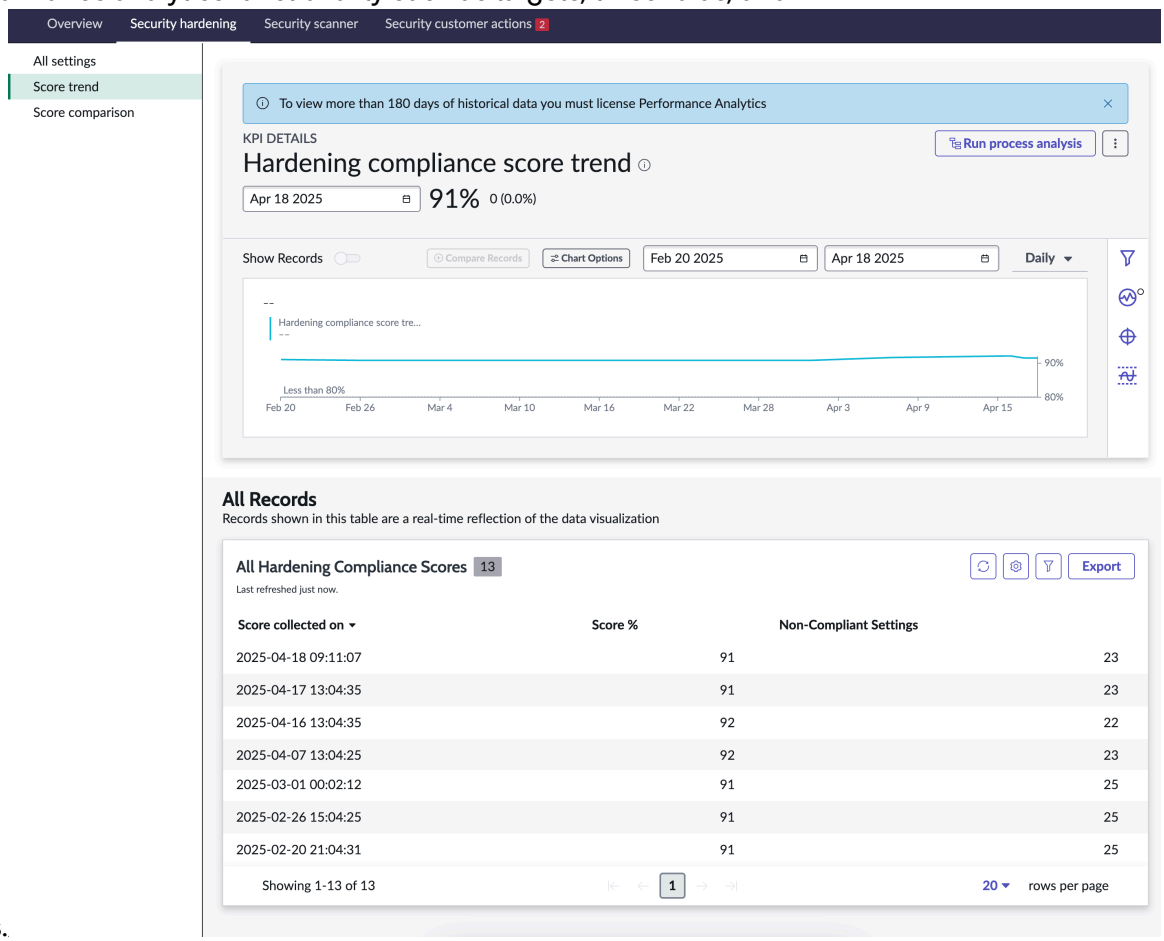
Procedure

1. Navigate to **All** > **System Security** > **Security Center**.
2. In the **Security Consoles** section, select the **Security configuration console**.
3. Select the **Security Hardening** tab.
4. Select **All settings**.
5. Select the **Show filter panel** button ( ).
6. In the **Filter** window, select **Advanced view**.
7. Create a filter showing only the hardening settings you want to review.
8. Once your filter is complete, select **Save Filter**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

9. Enter a name for your filter and select **Save**.

> **Note:** You may also make this list available to other users by setting permissions to **Everyone**, or **Group** to share with a specific group. These users must also have permission to use Security Center.



What to do next

After saving a filter you can load it in the **Advanced View** using the **Use existing filter** button.

Hardening compliance score trend

View the trends of your hardening compliance score over time in a chart or table.

See trends in your compliance score over time. Use the date picker to select a time range to analyze to gain insights into the data by applying performance analytics functionality such as targets, thresholds, and KPIs.

Compliance score chart

Use the **Chart options** button to specify what information to analyze and how to present the information.

Analysis

Select from the list of options. Some options may be unavailable depending on the selected chart type.

Target

Goals your organization wants to achieve. See Indicator targets.

Threshold

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Defines a normal range of scores for an indicator and alert you when a certain event occurs. See Indicator thresholds.

Forecast

Describes the ability to forecast future scores based on past behavior. See Performance Analytics scores forecasts.

Trend

Shows how the value of one or more items change over time.

Comments

Displays annotations on individual data points.

Labels

Displays scores related to visualizations.

Statistics

Displays statistics related to your compliance score.

Time series

Select which metric to display on the chart.

Score

Score for the Key Performance Indicator (KPI).

Change

Change of score for this indicator.

Change percentage

Change as a percentage of scores.

Chart type

Select a chart type to control how the information your selected is visualized. See Use cases for different time series visualization types.

All Records table

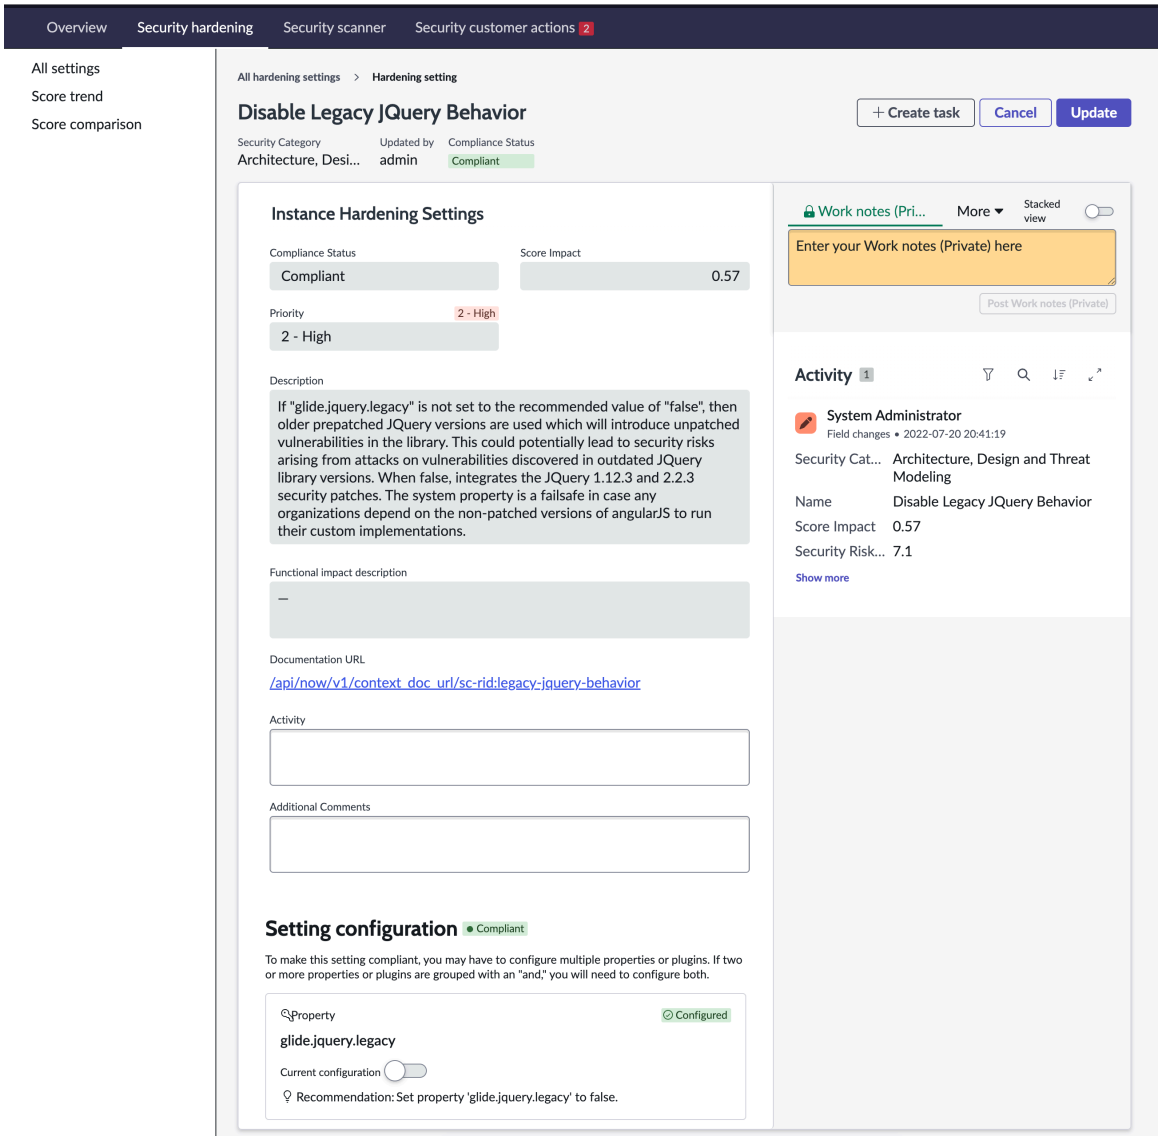
The All Records table displays the date on which the compliance scores were collected, the score percentages, and the number of non-compliant settings. You can use this table as another option to analyze the security posture of your instance over time.

Increase hardening compliance score

Increase your hardening compliance score by ensuring that the hardening settings are compliant with the system's recommendations.

Before you begin

Role required: admin



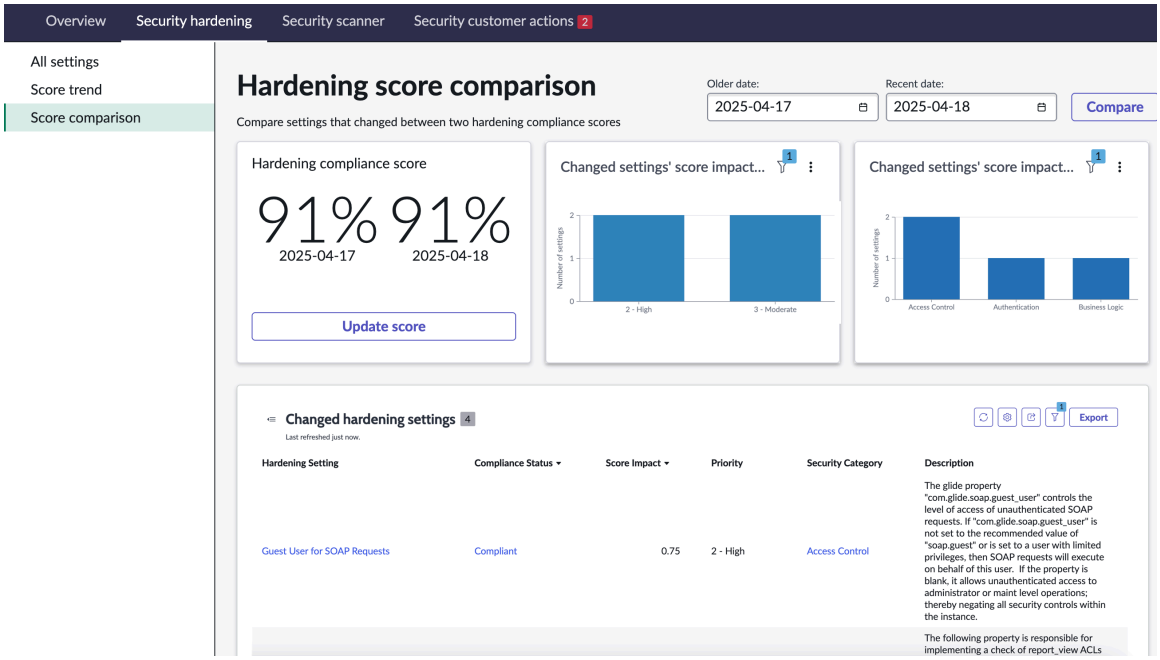
Identify non-compliant hardening settings with the highest score impact on your instance. Review them to see whether you can comply with system recommendations so that you can increase your overall compliance score.

Procedure

1. Navigate to **Hardening** > **All settings**.
2. Filter Compliance Status column to view only non-compliant hardening settings.
3. Select **Score Impact** to sort from largest to smallest.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Select settings and review the setting details to decide whether you want to comply with recommendations.



5. Make the hardening setting compliant.
6. If you update a non-compliant hardening score to make it compliant, go to the Homepage and select **Update score** to view the most up-to-date score.
   The hardening score is rounded up. A score of 86.75% will be rounded up to 87.

Hardening score comparison

Gain visibility to the health of your hardening settings and use this data to improve the security posture of your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

This page displays a summary of your hardening compliance and the changes made to your instance that impact this score.

The hardening score comparison page displays hardening settings with changes in compliance status between the dates selected in the **Older date** and **Recent date** fields. With this information you can see how they've impacted your hardening compliance score.

Hardening compliance score

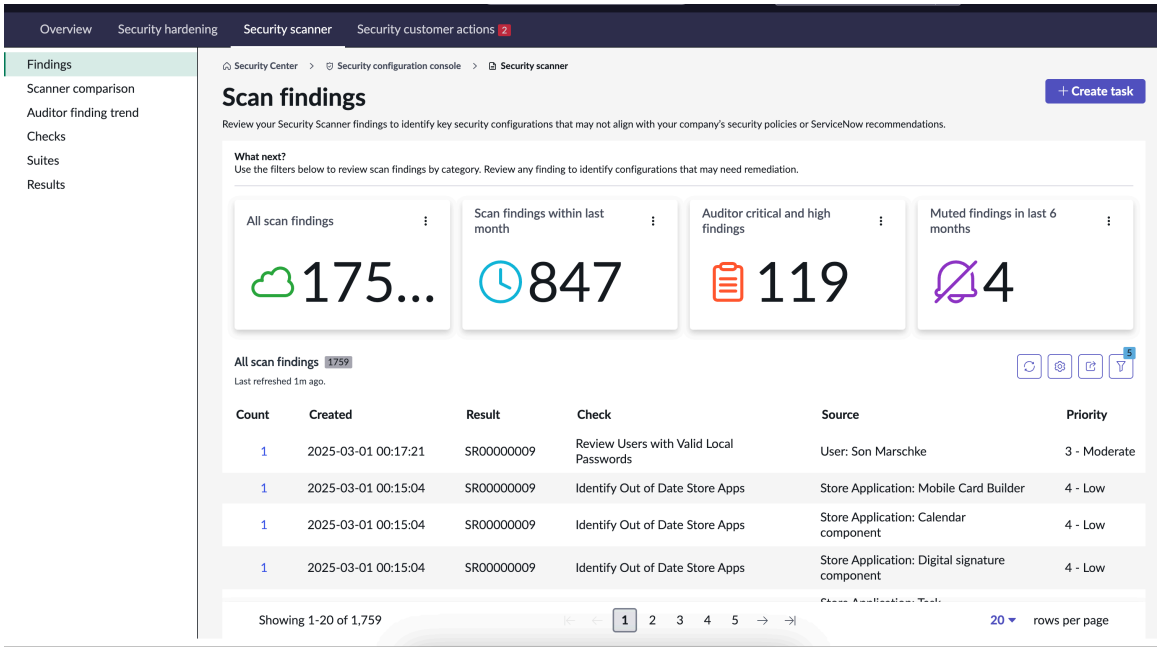
The card compares the compliance score of your instance on the selected dates as a percentage.

Changed settings' score impact by priority

Displays the number of hardening settings that have changed their compliance status since the last score update, organized by priority value.

Changed settings' score impact by security area

Displays the number of hardening settings that changed compliance status between the two selected dates, organized by security area.



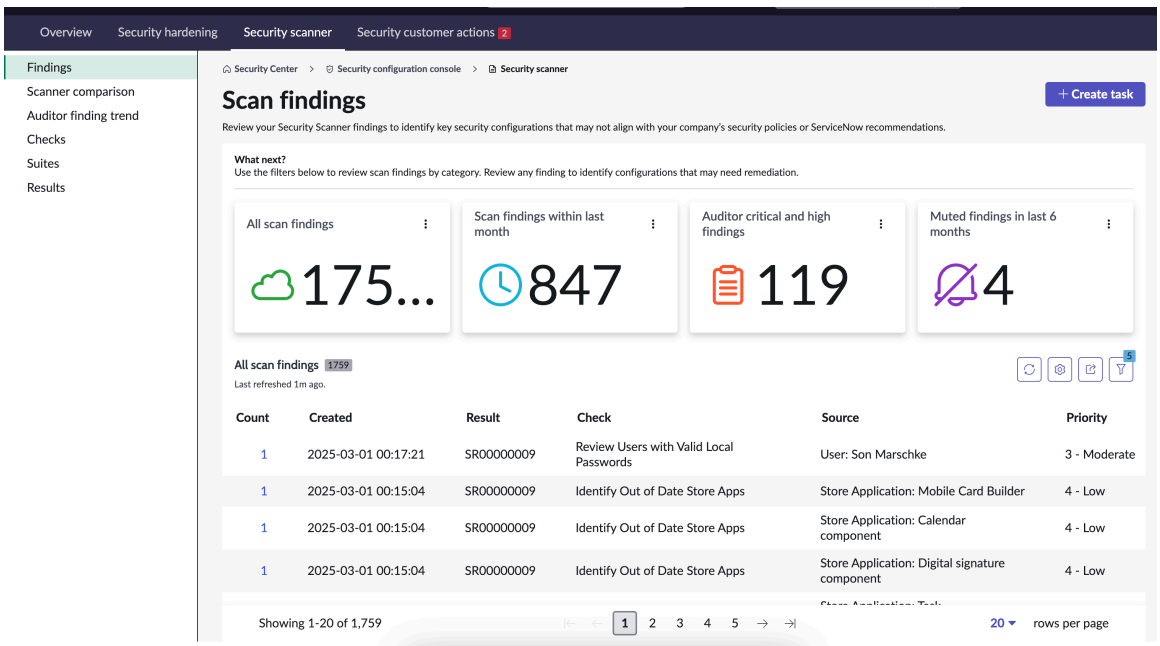
Changed hardening settings

Displays the list of hardening settings that have changed compliance statues between the selected dates. Review settings that became non-compliant and decreased your hardening comparison score for opportunities to make them compliant to increase your score. See Increase hardening compliance score.

Security scanner

Scan your instance against a set of security checks to identify misconfiguration. The scanner tool simplifies the process of creating different suites of checks for different use cases so that you can analyze the results over time.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

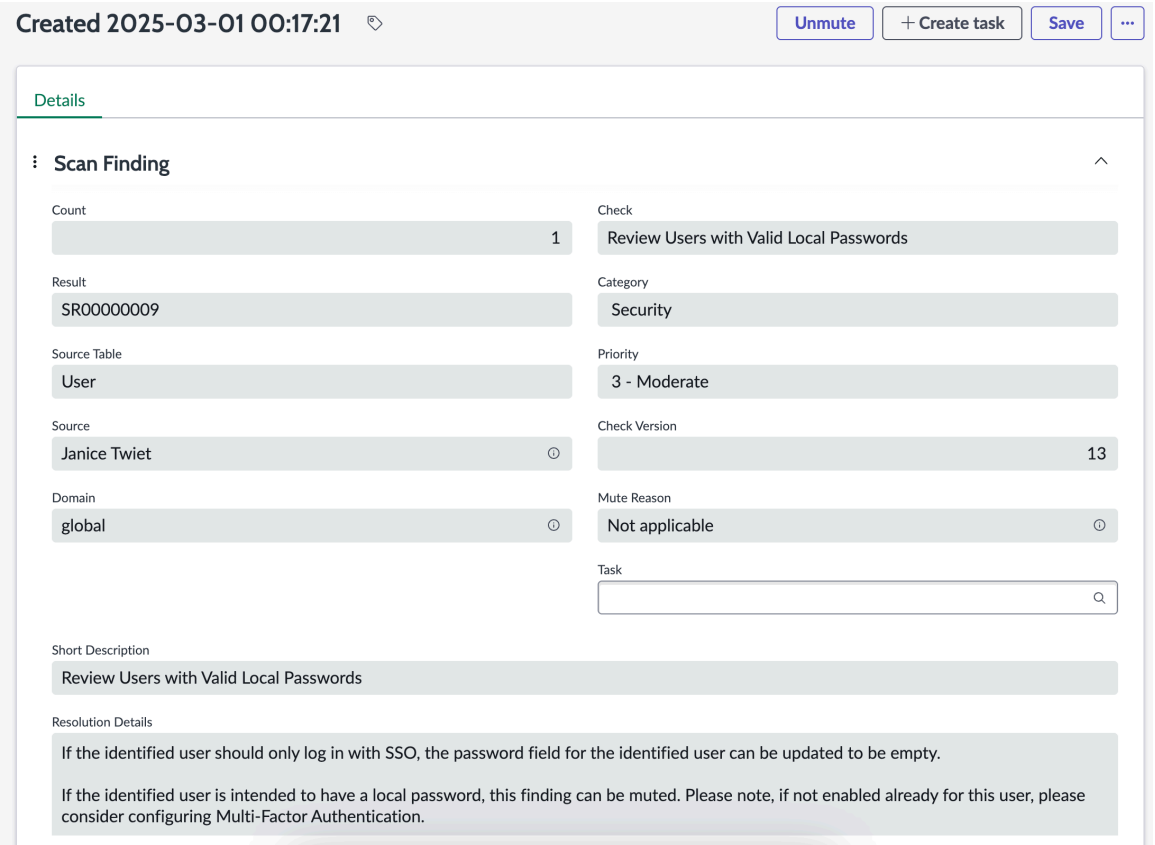


Security scanning is a method to investigate your instance for configurations that indicate security health issues. This method enables you to identify opportunities to implement security recommendations for your organization.

When accessing the scanner tool, there's no comparison available until you select the suite to be compared with at least two scan results of the suite. You can use the default suite and checks, or you can create your own custom checks and suites.

Scan findings

A finding is a reference to a record that has violated a rule from a check on the instance. You can find the source record and the number of times the record triggered the rules of a given check.



Navigate to the **Findings** tab to view scan findings in a list. The cards above the list provide a count of the findings that match specific criteria listed on the card. Select any of these cards to filter the list to show only those that match the criteria.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Select the **+Create task** button to create a Security Task to resolve a finding. This button appears both on the list and within the finding record. For details on Security Tasks, see Security Tasks.

Scan findings

Select a link under the **Count** column to view a finding record, which displays granular details related to a specific finding.

Check

List of checks associated with the scan.

Category

Security category associated with the scan. For example, access control or malicious code.

Count

Number of times the record violated check rules.

Priority

Severity of the security risk: 1 is highest priority while 4 is lowest.

Result

Status and type of scan.

Check Version

Version of the check.

Source Table

Record that has violated a rule from the check.

Mute Reason

Reason for muting the finding.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Source

Date the finding was created.

Task

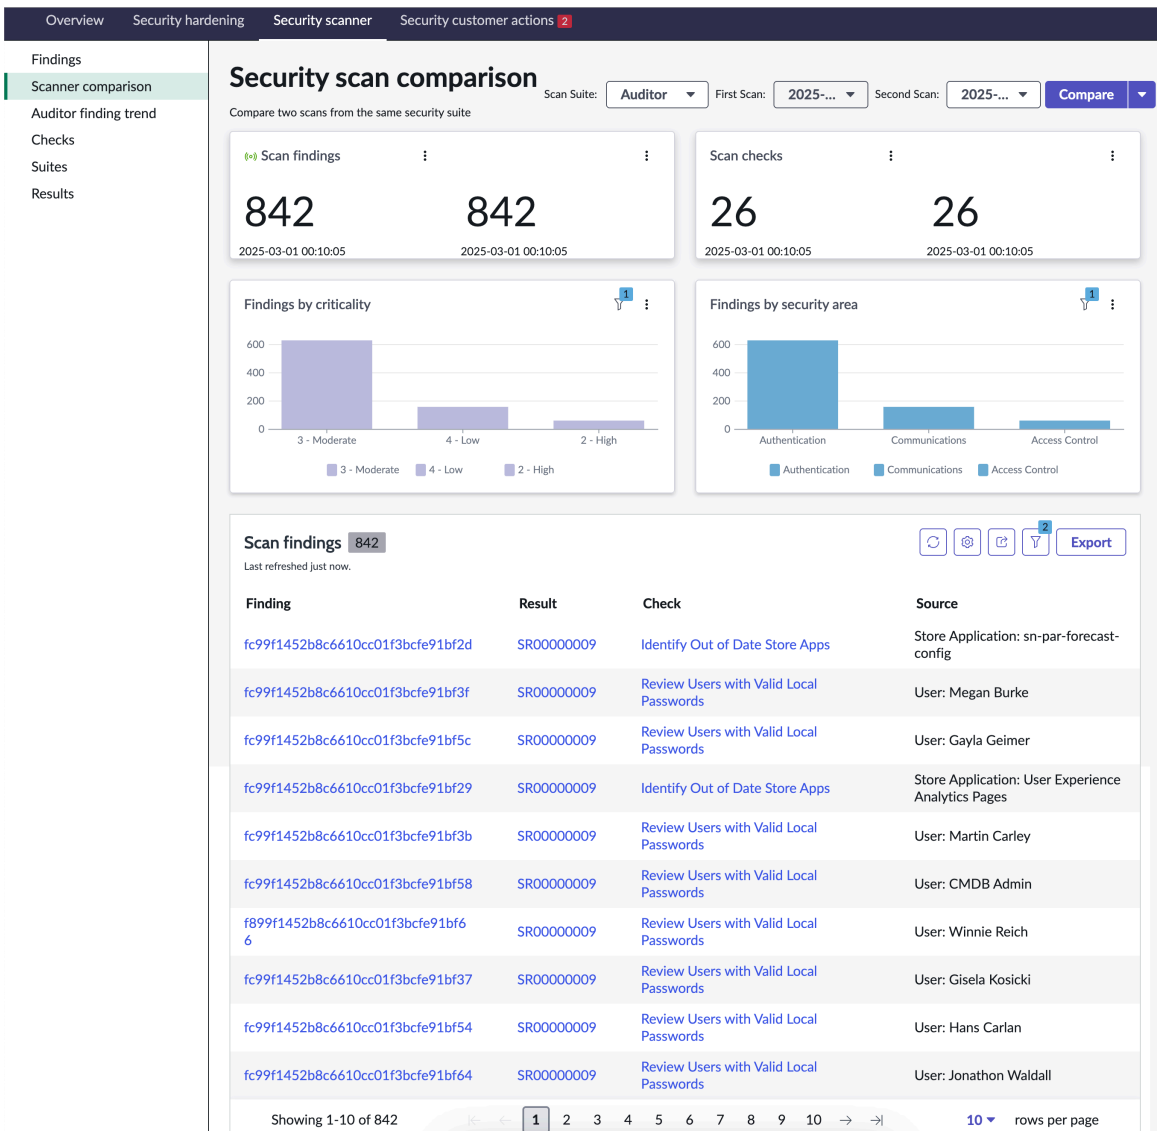
Task record associated with the scan. Used to facilitate task assignments from the finding of a record.

Domain

Which domain the scan is applied to.

Short Description

Brief explanation of the scan.



Resolution Details

Instructions on how to resolve issues reported by the scan.

Findings can be muted by selecting the **Mute / Unmute** button. When muting a scan finding, you're prompted a reason for muting the finding. Findings muted in the last six months are available in the muted findings card in the **Scan Findings** page.

Security scan comparison

Compare two scans of the same security suite to gain visibility to the health of your hardening settings and improve the security posture of your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important: This page appears empty if you don't have two or more instances of the same scan to compare. Run a scan at least twice to view a comparison on this page.

Select a scan in the **Scan Suite** list, then select a **First Scan** and **Second Scan** to begin a comparison.

The security scan comparison page displays the security changes in your hardening settings between the first and second scans. Below is an explanation of each card:

Scan findings

Number of findings in the selected scan at each selected date.

Scan checks

Number of scan checks performed in the selected scan at each selected date.

Changed findings by criticality

Chart displaying all findings organized by criticality.

Changed findings by security area

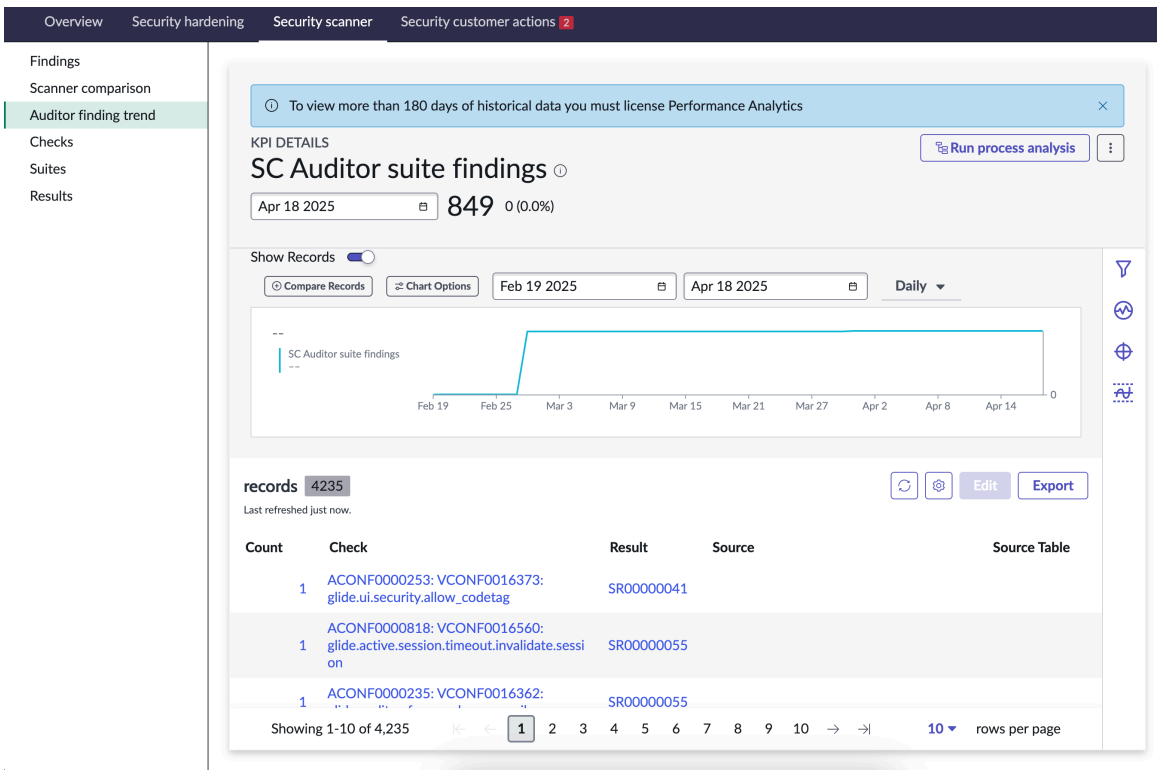


Chart displaying all findings organized security area.

Scan findings

List of all scan findings. Select a finding, scan result, or check to view the associated record and find additional details. Use the bottoms in the upper right to filter, refresh, or export the list.

Auditor suite findings

Review Security Center Auditor suite findings over time.

SC Auditor suite findings chart

The page shows SC Auditor suite findings compared between the two selected dates.Use the **Chart options** button to specify what information to analyze and how to present the information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Analysis

Select from the list of options. Some options may be unavailable depending on the selected chart type.

Target

Goals your organization wants to achieve. See Indicator targets.

Threshold

Defines a normal range of scores for an indicator and alert you when a certain event occurs. See Indicator thresholds.

Forecast

Describes the ability to forecast future scores based on past behavior. See Performance Analytics scores forecasts.

Trend

Shows how the value of one or more items change over time.

Comments

Displays annotations on individual data points.

Labels

Displays scores related to visualizations.

Statistics

Displays statistics related to your compliance score.

Time series

Select which metric to display on the chart.

Score

Score for the Key Performance Indicator (KPI).

Change

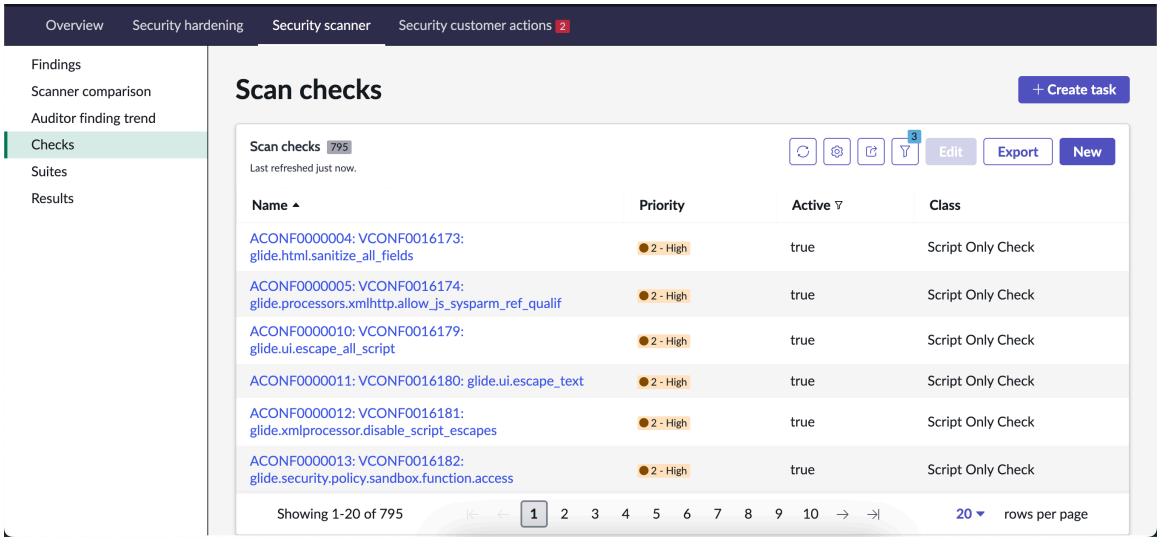
Change of score for this indicator.

Change percentage

Change as a percentage of scores.

Chart type

Select a chart type to control how the information your selected is visualized. See Use cases for different time series visualization types.



Records list

Lists the checks performed as part of the suite.

Scan checks

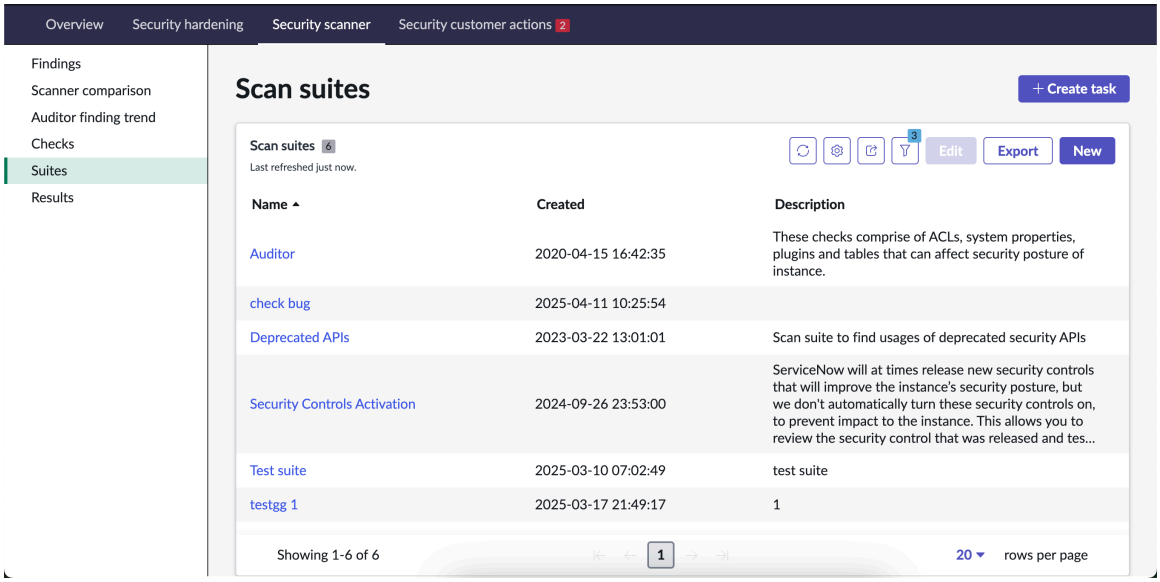
Use checks to detect anomalies within an instance, running against tables, records, or metadata.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Checks are rules designed to detect anomalies within an instance. Select a check on the list to view details including what the check evaluates, and possible steps to correct the issue if the check returns any findings.

Select the **+Create task** button to create a Security Task related to a scan check. For details on Security Tasks, see Security Tasks.

Checks are divided into four classes to identify issues and implement security recommendations for your organization: table checks, column type checks, script only checks, and linter checks.

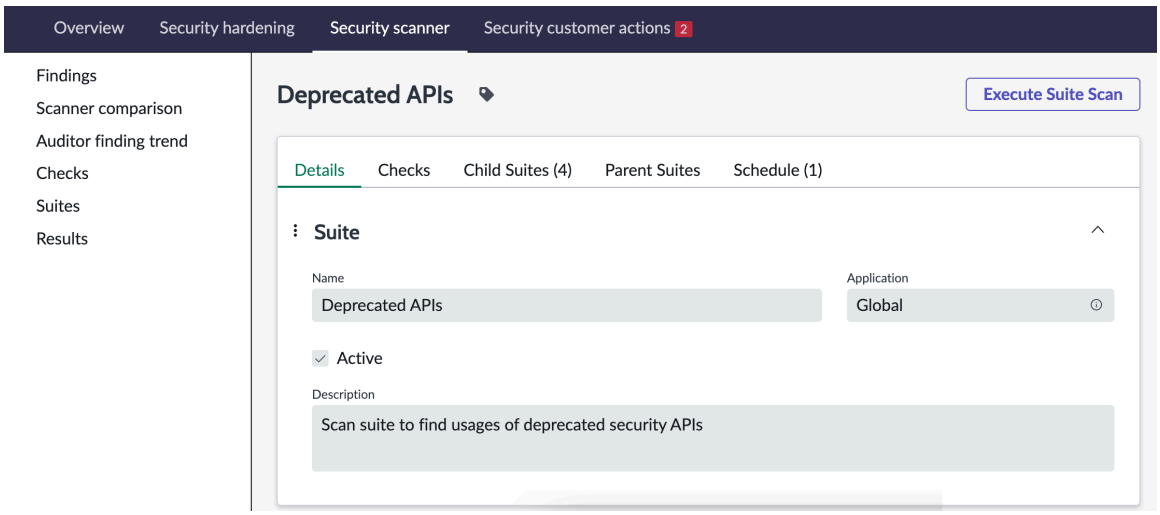


Check classes

Check class	Description
Table checks	Use this check class when you know the specific tables and checks you want to test.
Column checks	Use this check class to implement the rule you created to iterate all records matching the target column field type.
Script checks	Use this check class to verify meta data, configurations, and execute complex checks by writing your own checks.
Linter checks	Use this check class to identify any issues in a script. When a linter check is run on a record, an abstract syntax tree for its code is generated which can be used to analyze issues with the code.

Scan suites

Review details on the scan suites available on your instance.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Scan suites are collections of security center checks that execute together. You can use base system suites or create your own by cloning an existing suite and updating the checks made in the clone. For details, see Create a scan suite.

Select the **+Create task** button to create a Security Task related to a scan suite. For details on Security Tasks, see Security Tasks.

Scan suite details

Select the **Name** field of a suite to view the suite details. This page provides details on the scan suites in a tabbed interface. In the tabbed page, you can find this information:

Details

Details on the suite include its name, application, and description.

Checks

List of the checks included in this suite. Details on individual checks are the same as are found in Scan checks.

Child Suites

List of child suites associated with this suite. When you execute this suite, all child suites also execute.

Parent Suites

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

List of suites in which this suite is a child suite. When you execute a parent suite, this suite is also executed.

Schedule

Details of the scheduled execution of this suite.

Access Controls Auditor checks

Learn about the checks available in the default Access Controls Auditor Suites, what criteria they evaluate, and how they can be used to improve the security of your instance.

Access Control List rules (ACLs) restrict access to data by requiring users to pass a set of requirements before they can interact with it. Access Controls Auditor checks evaluate your instance according to the eight criteria listed in the following table. Use the findings on these checks to improve the security of your instance.

Access Controls Auditor checks

Check Name	Check Criteria	Description
All Processors of type - SCRIPT must be protected with CSRF Token	Checks for Processors with the **SCRIPT** type that aren't protected with a CSRF token.	All Processors with the **SCRIPT** type should be protected with a Cross-site Request Forgery (CSRF) token. These processors should have the CSRF option checked, which prohibits the processor from running unless the instance uses a CSRF token.
Can Contribute / Cannot Contribute user criteria to be defined on each knowledge	Checks for knowledge base records that don't have **Can Contribute** or **Cannot Contribute** user criteria defined.	Each knowledge base should have either **Can Contribute** or **Cannot Contribute** user criteria defined. Otherwise, any user can contribute content to a knowledge base with no Contribute criteria defined.
Empty ACLs	Checks for Access Control List (ACL) records that have no security attribute, no role, or the **public** role.	Leaving ACLs empty or using the **public** role may provide open access to any content protected by this ACL.
Access Controls on Client callable Script Includes	Checks for client-callable script includes that aren't secured by ACLs.	All client callable script includes should be secured with an ACL using required roles.
Access controls on UI Pages	Checks for UI Pages that aren't secured by ACLs	Without an ACL securing access to a UI Page, that UI Page is accessible to all logged-in internal users. Without any restrictions logged-in users can potentially make unauthorized changes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Access Controls Auditor checks (continued)

Check Name	Check Criteria	Description
Access controls on Tables	Checks for tables without ACLs	Tables should be secured with ACLs. Access to data stored in tables should be limited only to users that need it.
User Account shouldn't have both Internal and External roles	Checks for user records with both **Internal** and **External** roles assigned	Internal user roles are intended for users within your company. External user roles are intended for external personnel, such as customers and partners.
Publicly accessible knowledge base and articles	Checks for publicly accessible knowledge bases and knowledge base articles	Publicly accessible knowledge bases and articles are visible to all users in the instance. Increase security by limiting knowledge bases and articles to the specific audience that needs them.

Auditor checks

Use the Auditor suite to SecureCheck to detect misconfiguration that can impact the security posture of your instance.

Check information

Access Controls Auditor checks

Check Name	Description	Scan finding type
Identify out of date store apps	Identifies apps activated on your instance that have updated versions available. Verify you're running to the most up-to-date versions of store applications, which can include fixes to potential security issues.	Resolution Recommended
Insecure GlideRecord calls	Identifies scripts that are directly invokable by end users (such as Client-Callable Script Includes, Widgets, Processors, REST Endpoints) These scripts should respect ACLs and use GlideRecordSecure or GlideRecord with canRead, canWrite, canCreate, canDelete.	Resolution Recommended
Review allowed JavaScript libraries	Identifies scripts where JavaScript Content Access Control is used to allow or deny specific third-party JavaScript libraries.	Resolution Recommended

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Access Controls Auditor checks (continued)

Check Name	Description	Scan finding type
	Review instance customizations to verify that libraries aren't in use before blocking access. The JavaScript Content provider Access Tracking [sys_js_content_provider_access_tracking] table can be reviewed to see the last date that the library was accessed. **Note:** This check can be ignored in instances initially provisioned on Tokyo or later. Records on the associated table have deny rules set by default. In instances initially provisioned prior to Tokyo, there may be allow rules in the JavaScript Access Control tables.	
Review client callable script includes with no corresponding ACL	Identifies client callable script includes that don't have a corresponding ACL. These scripts use the default ("*") client callable script include ACL. For these scripts, create ACLs that defines the appropriate criteria for access to verify that only expected users can interact with the functionality provided.	Resolution Recommended
Review custom tables with record producers and no business rule	Identifies record producers that don't have additional server-side validation. This check identifies custom tables with a Record Producer but without an associated business rule. These may enable users to submit unexpected data into the associated table.	Resolution Recommended
Review empty ACLs	Identifies ACL records which have no script, condition, security attribute, or role, or ACLs with the **public** role. Leaving ACLs empty or using the **public** role provides open access to any content protected by this ACL.	Resolution Recommended
Review fields with HTML Sanitization disabled	Identifies HTML fields where HTML Sanitization is inactive. HTML sanitization removes or replaces potentially harmful elements and attributes within HTML code. Review HTML fields where	Resolution Recommended

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Access Controls Auditor checks (continued)

Check Name	Description	Scan finding type
	sanitization is inactive to confirm whether this configuration is necessary.	
Review inactive security feature plugins	Identifies plugins that aren't activated that provide additional, configurable security controls. The findings produced by this check are provided for informational purposes. Before enabling one of the identified plugins, verify that the plugin meets your use cases or requirements. You can mute these findings if you don't have a use case for the identified.	Inform
Review large allowed IP address ranges	Identifies IP Address Access Control Ranges that contain a large number of IP Addresses. **Note:** If you're seeing a large number of false positives, consider adjusting the largestExpectedCIDRBlock variable for your specific business needs. Classless Inter-Domain Routing (CIDR) blocks contain a larger amount of IP addresses as the number decreases. For example, the CIDR block size 8 is larger (contains more IP addresses) than the CIDR block size 16. Review and confirm that the current configuration aligns with your business needs.	Review and Decide
Review public GraphQL schemas	Identifies public GraphQL schemas in the GraphQL API [sys_graphql_schema] table. These schemas can be configured to be available without authentication. Depending on the endpoint's functionality, this may allow unauthenticated users to perform unexpected actions or interact with unexpected data.	Review and Decide
Review public knowledge base articles	Identifies knowledge bases and knowledge base Articles configured to enable access to unauthenticated users. Review and confirm that the current configuration aligns with your business needs.	Review and Decide

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Access Controls Auditor checks (continued)

Check Name	Description	Scan finding type
Review public REST API endpoints	Identifies Rest API Endpoints in the Scripted REST Resource [sys_ws_operation] table that are configured to be available without authentication. Depending on the endpoint's functionality, this may allow unauthenticated users to perform unexpected actions or interact with unexpected data.	Review and Decide
Review public Service Portal pages	Identifies Service Portal pages that are made public. Service Portal pages are made available to unauthenticated users by setting the "public" field to "true." Review and confirm that the current configuration aligns with your business needs.	Review and Decide
Review public UI Pages	Identifies UI Pages that are made public. UI Pages can be made available to unauthenticated users using the [sys_public] page. Review and confirm that the current configuration aligns with your business needs.	Review and Decide
Review roles that contain the 'admin' role	Identifies any roles (Roles [sys_user_role] table) that contains the **admin** role. The **admin** role grants users administrative privileges and should be used only when necessary. Review and confirm that the current configuration aligns with your business needs. If this is an intentional configuration, this check can be muted.	Review and Decide
Review UI Pages without corresponding ACLs	Identifies UI Pages that don’t have an ACL for that UI Page. UI Pages that don’t have a specific ACL default to a generic UI Page ACL, which may grant access to unintended users.	Resolution Recommended
Review users with valid local passwords	Identifies users with locally set passwords. Users with local passwords may interact with the instance via APIs using the local credentials, even if local logins are disallowed.	Review and Decide

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

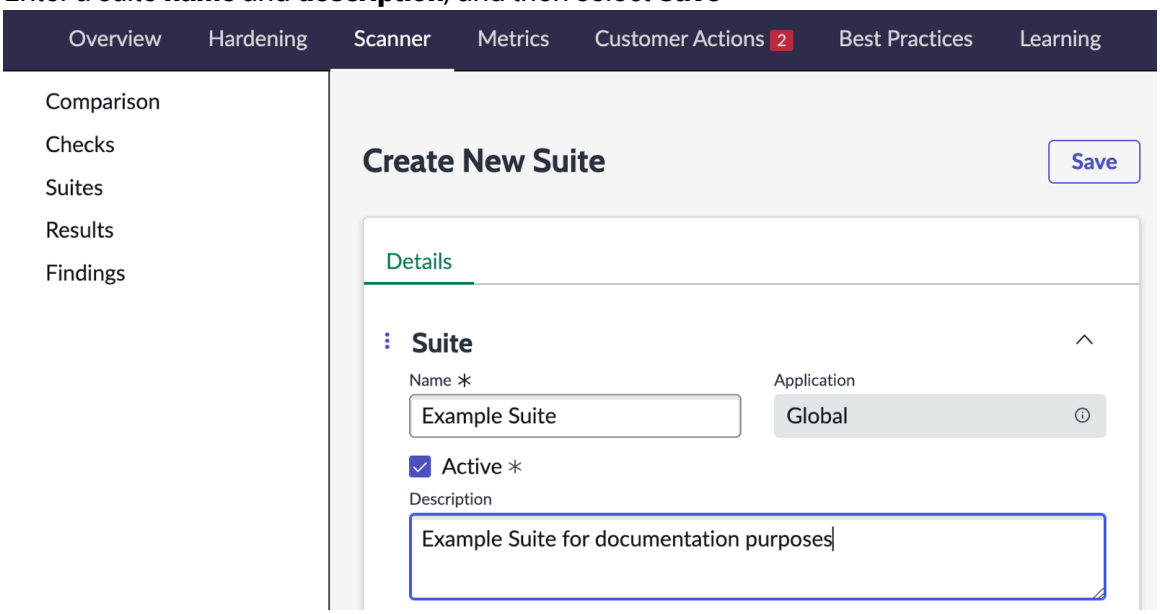
Access Controls Auditor checks (continued)

Check Name	Description	Scan finding type
	This password configuration is needed for integration user accounts to function correctly. Review these user accounts to verify that only intended users (such as integration accounts) can authenticate with local authentication.	
Rotate passwords stored with outdated hashing algorithms	Identifies user accounts with passwords created in previous versions of the ServiceNow AI Platform, which may have used what is now considered a legacy or outdated hashing algorithm. Accounts created on old platform versions that haven't rotated their passwords may still have passwords stored with a legacy hashing algorithm. Review the identified accounts created consider password resets.	Resolution Recommended
Securing record producers	Identifies insecure record producers. If not assigned to appropriate roles unauthorized users can access them, potentially revealing sensitive information. Assign appropriate roles to record producers to verify that they're accessible only to users that need them.	Resolution Recommended
UI action visibility	Identifies UI actions that can be accessed by a user with no roles who doesn't have read access to the table. These users may be able to alter data on a table they don't have access to via these UI actions. Verify that UI actions are only available to users with access to the table they affect.	Resolution Recommended

Create a scan suite

Create and schedule a custom suite so that you can analyze the security of your instance for your organization.

Before you begin



Role required: admin or sn_vsc.security_center_viewer.

A suite is a collection of checks that can be used for a scan. View a list of scan suites organized in a table by navigating to **Scanner** > **Suites**. Create your own suites or to use the default suite, Auditor. Auditor is a default base system suite that contains checks for security best practices. These checks consist of system properties, plugins, and tables that can affect the security posture of your instance. The following steps show how to create a suite along with the several options available for configuring them.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. In Security Center, select the **Scanner** tab, then select **Suites** in the panel on the left side of the screen.
2. In the **Scan Suites** page, select the **New** button.
3. Enter a suite **name** and **description**, and then select **Save**

After selecting **Save**, configuration options for the suite display in a tabbed interface.

4. Select the **Checks** tab.
   Use this tab to add checks to your suite.
   a. Select **Edit**.
   b. Select the checks that you want to add, and then select Add (**>**) to place it in your suite.
   c. **Save**.
5. Select the **Child Suites** tab.
   Use this tab to add child suites. Suites added as child suites are also executed.when this suite is used in a scan.
   a. Select **Edit**.
   b. Select the child suites that you want to add, and then select the Add (**>**) to place it in your child suite.
   c. **Save**.
6. Select the **Parent Suites** tab.
   Use this tab to add parent suites. Parent suites that are executed in a scan will also execute this suite.
   a. Select **Edit**.
   b. Select the child suites that you want to add, and then select Add (**>**) to place it in your parent suite.
   c. **Save**.
7. Select the **Schedule** tab.
   Use this tab to set a time for your suite to execute.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Select **New**.

b. Enter details of the scheduled scan.
The time fields are in the format: hour:minutes:seconds.

c. **Save**.

Clone the access controls auditor suite

Clone and customize the default access controls auditor suite in your instance to create a new suite tailored to your organization's security practices.

Before you begin

Role required: admin

About this task

The default access controls auditor suite provided with your instance can't be modified. However, if you want to add, remove, or edit checks to align with your organization's security practices, you can duplicate the access controls auditor suites. Copying the access controls auditor suites enables you to customize it and create a new suite based on the default one. The access controls auditor suites includes checks related to security best practices, covering system properties, plugins, and tables that impact the instance's security posture. The following steps demonstrate how to duplicate the default access controls auditor suites to tailor it to your organization's requirements.

Procedure

1. Navigate to **All** > **Instance Scan** > **Suites**.
2. Select **New** and enter a name for your suite, along with an optional description.
3. Right-click the form header and select **Save**.
4. Add the checks needed for your scan.

   a. In the **Checks** tab, select **edit**.

   b. Add the conditions.
   For example, to add scan checks apply the following fields, operators, values, and conditions:

   [Category][is][Security] AND [Application][is][Global]

   For example, it should look like the following: `Category is Security And Application is Global`.

5. Select **run filter**.
6. Select the scan checks that you want to add from the collection list to the check list, and then select the add (>) button.
7. Select **save**.
   The suite with your custom checks added have been created.
8. Select **Execute Suite Scan**.

© 2026 ServiceNow, Inc. All rights reserved.

View the Access Controls Auditor Suite

View the checks available in the default Access Controls Auditor Suites to understand which checks are executed when this suite runs.

Before you begin

Role required: admin

About this task

The steps you need to complete to access the default access controls auditor suites within your ServiceNow instance.

Procedure

1. In Security Center, select the **Scanner** tab, then select **Suites** from the panel on the left.
2. In the **Scan Suites** page, select **Auditor** from the list.
3. To review the suite checks, select the **Checks** tab.
   You should see the list of 8 checks available for the suite.
4. Select the name of a check you want to analyze.
5. Analyze the fields associated with the check.

Name	Description
Name	Name of the check.
Application	The application to which the check belongs (Security Center).
Category	Category associated with the check.
Priority	The level of urgency.
Version	Version number of the check.
Active	The status of the check, for example, active or inactive.
Short Description	A brief summary of the check.
Description	A more comprehensive summary of the check.
Resolution Details	Mitigated potential security incidents.
Documentation URL	Links to related documentation in the product documentation or Knowledge Base (KB) articles.
Run Condition	Conditions that trigger the start of the checks.
Table	The table to which the check belongs.
Conditions	Conditional logic applied to the checks.
Advanced	Advanced configuration options.

Reschedule a scan suite

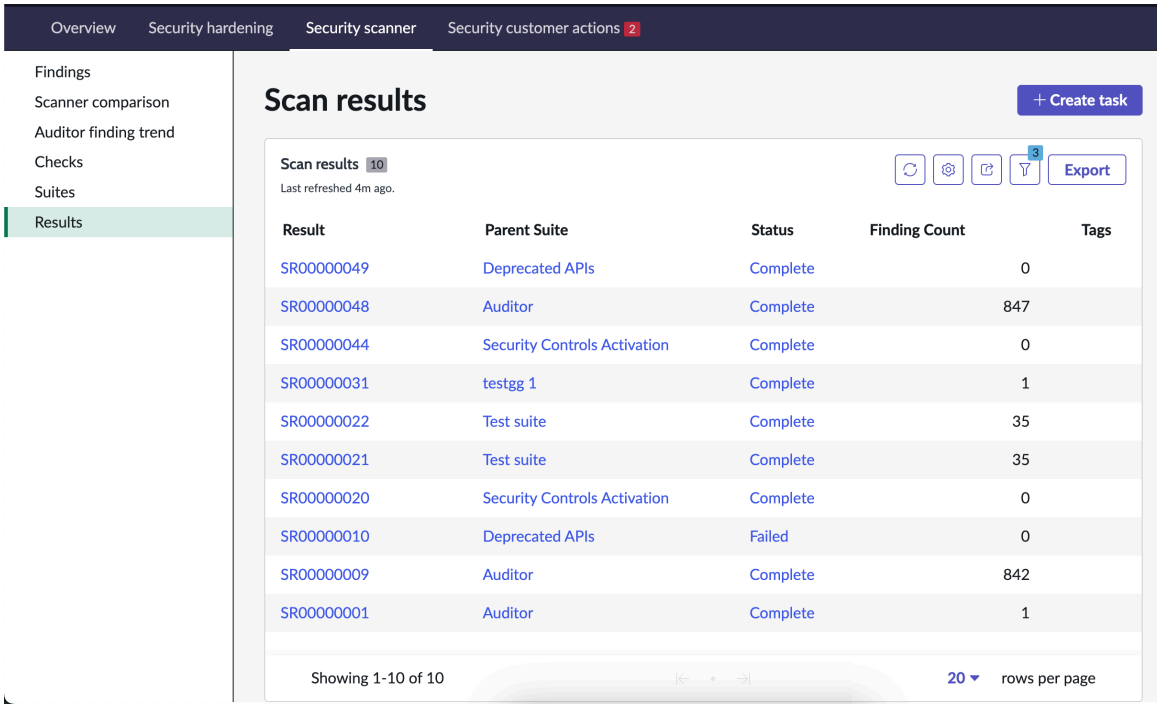
Change the schedule of your scan suites to suit your needs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

Role required: admin, sn_vsc.security_center_viewer

Procedure



1. Navigate to **All** > **System Security** > **Security Center**.
2. In the **Tools** section, select **Security scanner**.
3. Select **Suites** in the menu on the left edge of the screen.
4. Open the suite you want to reschedule.
5. Select the **Schedule** tab.
6. Select an existing schedule, or select **New** to create a new schedule.
7. In the **Scheduled Scan** form, fill in the fields as needed.

Field	Description
Name	Name of the scan schedule
Run	Select the how often your suite will run. **Note:** Additional fields will appear to help define your schedule. These fields vary depending on your selection.
Active	Whether the schedule is active. Inactive schedules are never executed.
Conditional	Select to enable the **Condition** field, where you can define a scripted condition for your schedule.
Condition	A scripted condition for your schedule. The suite will only run when the script evaluates to `true`.
Run as tz	Which timezone the schedule uses when determining when to run.

Scan results

View data related to your scan results from a single view.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

A scan result reports the status and type of the scan. You can also see all the checks that ran as part of the scan and all other information related to the scan such as errors and scan logs.

You can find your scan results dashboard by selecting the **Scanner** tab in Security Center, then selecting **Results** in the left panel. The scan results are listed under the **Scan results** list. Select a result to drill in and view the details, which are separated into tabbed sections.

Details

Overview of the scan results including the status, type, and execution time in seconds.

Scan Findings

Findings encountered during the execution of the checks.

Suites

Displays the suites that ran as part of this scan.

Checks

Displays the checks that ran as part of this scan.

Failures

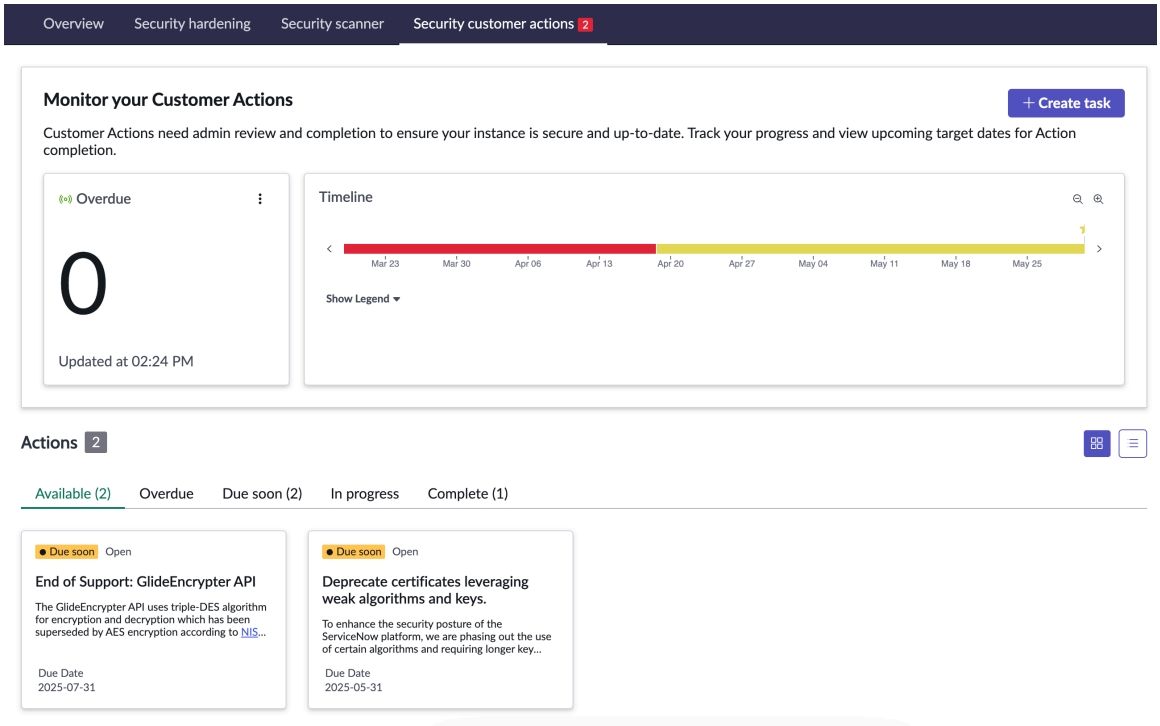
Displays the checks that failed during the scan and the reason of its failure in the form of an error message.

Scan Log

Displays messages output during the scan.

Scan Statistics

Displays statistics related to the scan.



Targets

Displays all the targets against which the checks have executed.

Customer Actions

Use the Customer Actions tool to implement important security updates based on your instance and the configuration of plugins.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

ServiceNow updates your instance with family releases and patches to keep base system platform code and functionality current and secure. However can be additional actions you can take to secure your instance that are unique to your custom instance configuration. These recommended updates are found in the Customer Actions tool.

Customer Actions vs. Family releases and patches

Feature	Customer Actions	Family releases and patches
Definition	Manual, guided tasks for admins to implement important security changes.	System-driven updates applied automatically during family releases or patches.
Purpose	Address security risks that can't be resolved by ServiceNow upgrades alone. Designed to avoid disrupting custom configurations.	Keep platform code and functionality current and secure.
Examples	Deprecating weak certificates, enforcing multi-factor authentication (MFA), disabling insecure protocols.	Platform version upgrades, patch-level fixes, backend security enhancements.

Access this tool by navigating to **Customer Actions** within Security Center.

Elements of the Customer Actions tool

Create Task button

Use the **+Create task** button to create a Security Task to complete a Customer Action. For details, see Security Tasks.

Overdue actions

A count of the number of Customer Actions that are part their due date. Select the overdue actions card to see a list of past due Customer Actions.

Customer Actions timeline

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

A timeline of Customer Actions so that you can prioritize when to implement the steps. The timeline in the preceding image shows the Customer Actions that are overdue, and the ones that are due soon.

Actions tabs

A tabbed interface showing Customer Actions by category:

- Available
- Overdue
- Due soon
- In progress
- Complete

Select a tab to view a list of actions in each category.

For details on how to review individual Customer Actions, see View Customer Actions.

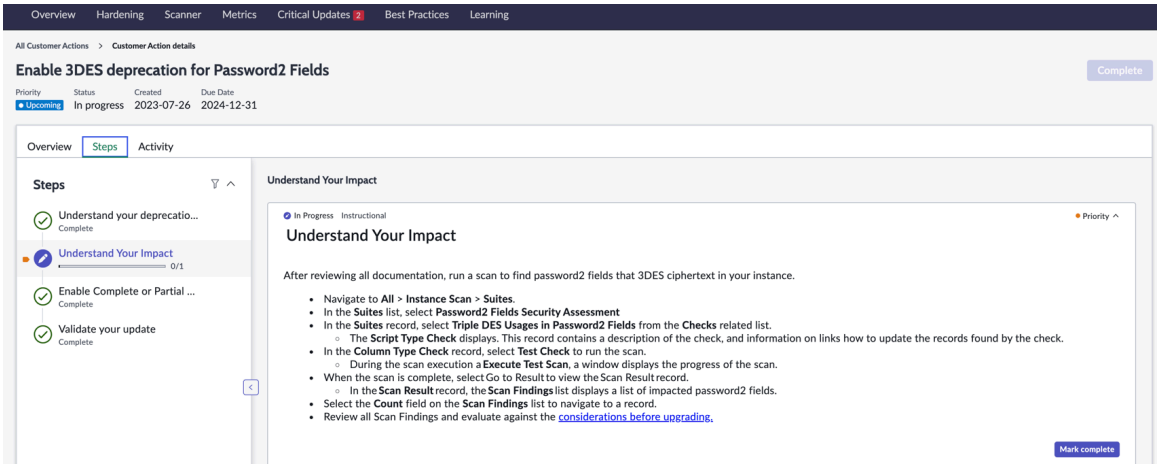
For information on how to apply the changes recommended by Customer Actions, see Implement Customer Actions.

Implement Customer Actions

Learn how to implement Customer Actions on your instance to increase its security posture.

Before you begin

Role required: admin



About this task

Customer Actions provides you step by step instructions for how to implement the changes on your instance to increase your security posture. Customer Actions pulls relevant content from the product documentation to guide you through each step of the implementation process. Follow the steps below to learn how to implement a Customer Action.

Procedure

1. Navigate to the **Customer Actions** app.
2. Select a Customer Action to implement.
   Under the **Updates** section, the Available tab lists all the Customer Actions on your instance. Click on a Customer Action under this tab to view the instructions.
3. Read the overview to learn why the Customer Action is needed, and to prepare for implementing the steps.
   Click on **Go to next step** to progress to the implementation details.
4. Implement the update steps.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Read each group of instructions and implement them within your instance.

b. Click **Mark complete** when you are done with a set of instructions.

c. Repeat steps a-b until you have completed all of the update steps.

d. Click **Complete**.
The Customer Action should appear in the **Complete** tab.

View Customer Actions

See details of all of the activity related to your Customer Actions.

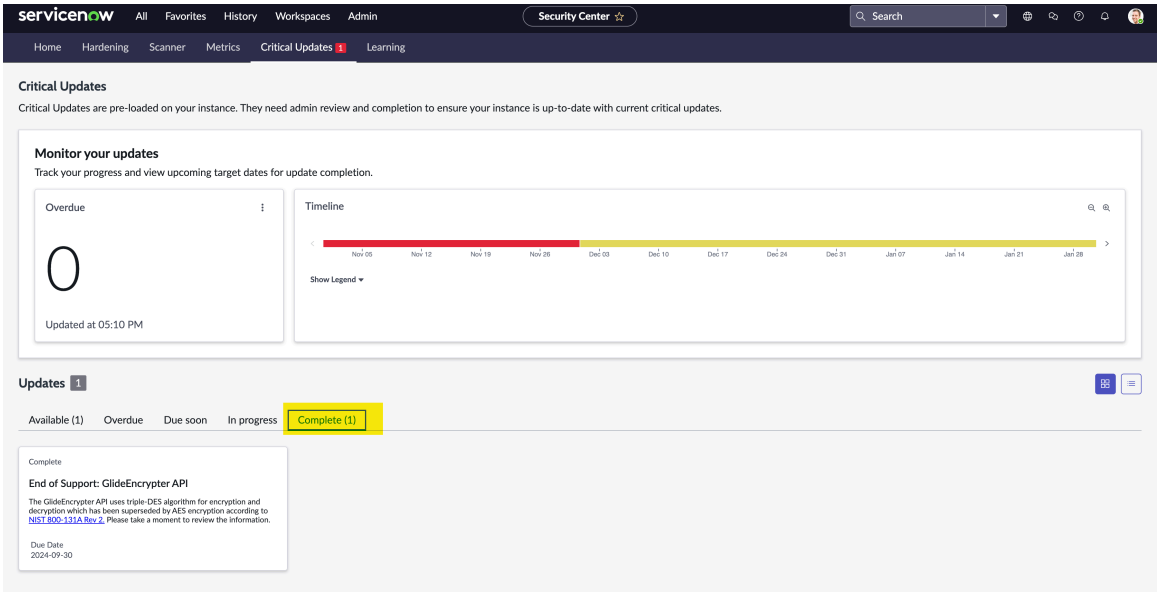
Before you begin

Role required: admin

About this task

The activities will be listed from newest to oldest so that you can analyze the most recent activity first. Each update to an activity is timestamped, and you can use search and filter to query for specific information.

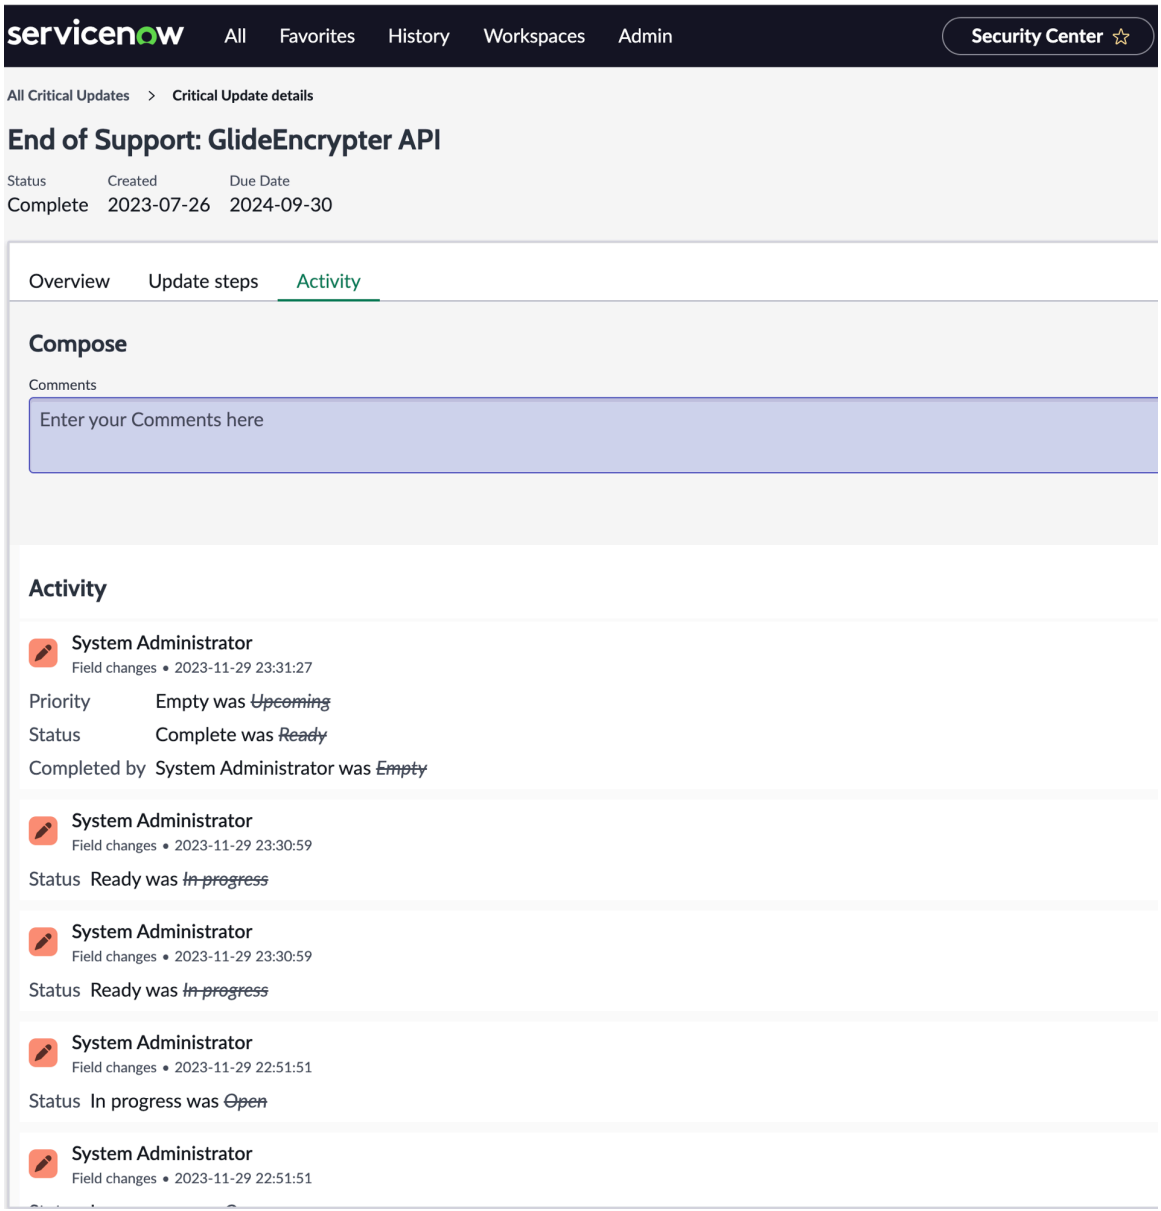
Procedure



1. Navigate to the **Customer Actions** app within Security Center.

2. Navigate to the **Updates** label of Customer Actions.

3. Click a state, and then select a Customer Action from that state.



In the example below, the **Complete** state is selected and then the Customer Action for **End of Support: GlideEncrypter API** is selected.

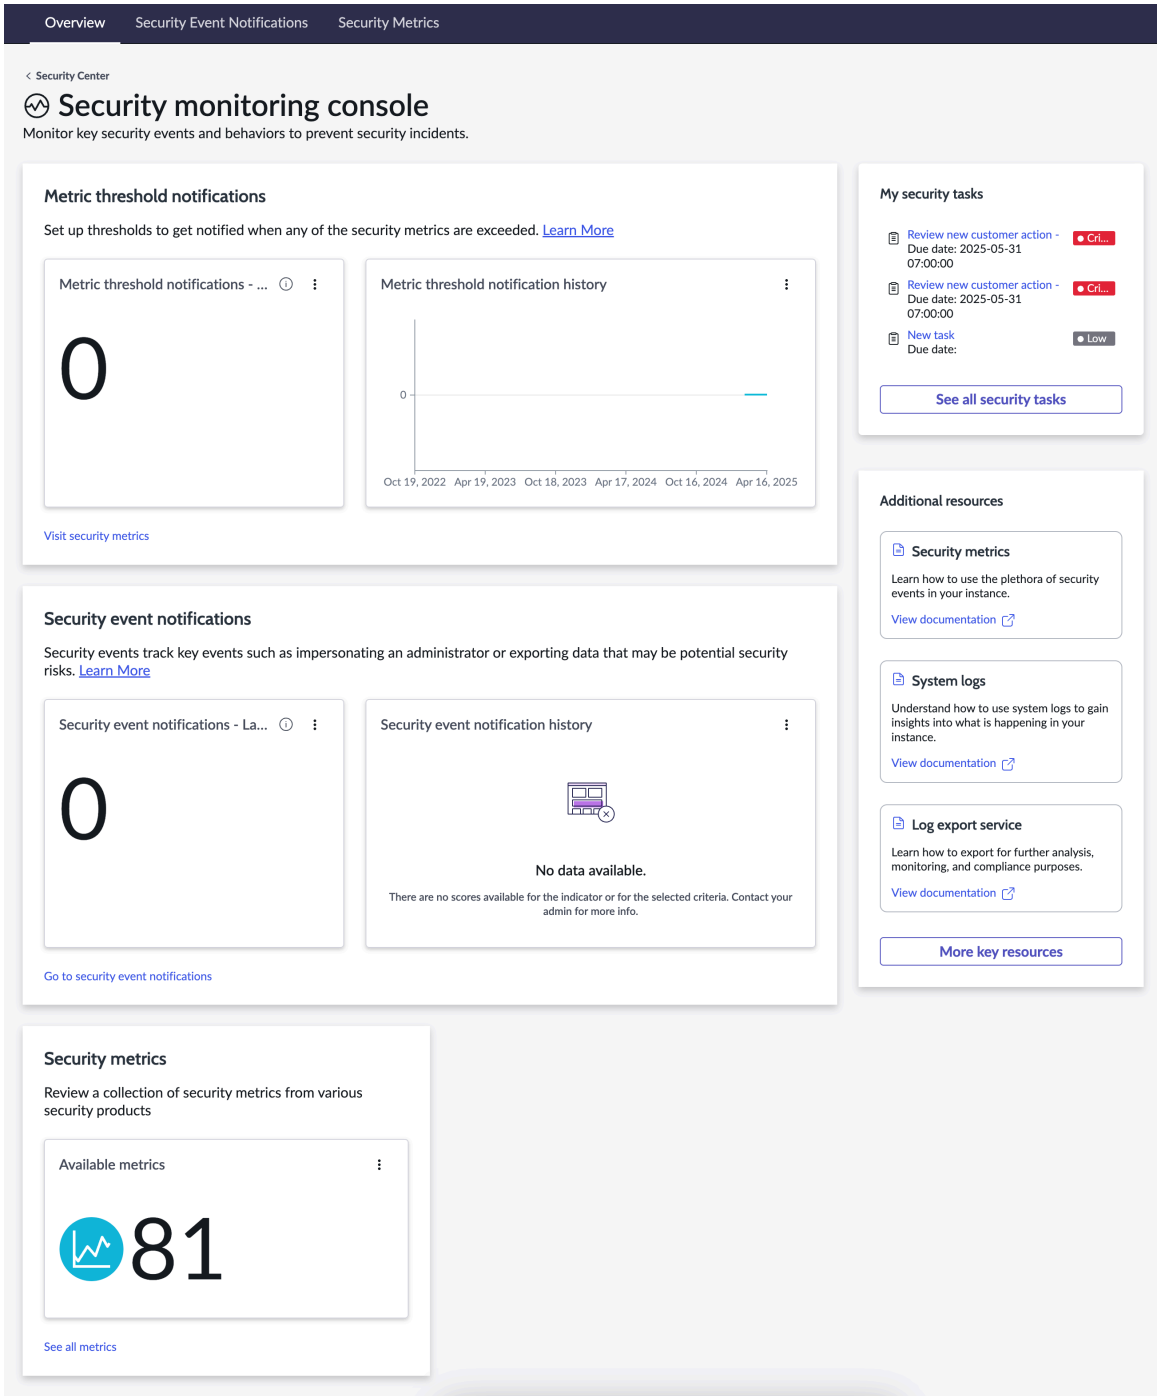
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



All of the activity related to a Customer Action is automatically recorded. In addition, you have the ability to add additional comments to activities.

Security monitoring console

Supervise security notifications and metrics to stay informed about potential security risks on your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The Security monitoring console is organized into sections, each with cards containing information on a specific aspect of security monitoring. Select the info (ⓘ) icon on any card for details on what each represents.

Navigation bar

Use the bar at the top of the page to navigate between the **Overview**, **Security Event Notifications**, and **Security Metrics** sections.

Metric threshold notifications

Learn about the metric threshold notifications on your instance in the Metric threshold notifications panel. Thresholds define a normal range of scores for an indicator and alert you

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

when certain events occur, like when a score reaches an all-time high. This panel displays the count of threshold notifications in the last seven days, and a chart showing the threshold count over time.

Select either card to open the Security metrics tab to see more detail on these notifications.

Security event notifications

Track security events such as impersonation or data exports in the Security event notifications section. This panel displays the count of security events in the last seven days, and a chart showing the count over time.

Select either card to open the Security metrics tab to see more detail on these notifications.

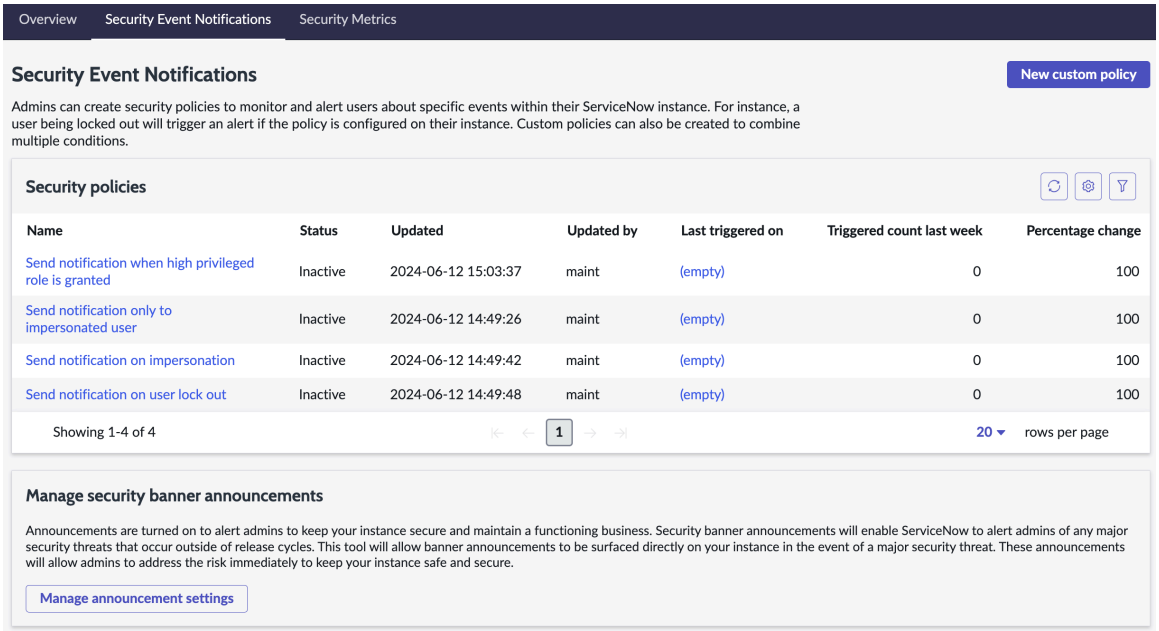
Security metrics

This section displays a count of available Security Metrics on your instance. Review a collection of Security Metrics from various security products.

My Security Tasks

View the most urgent Security Tasks assigned to you. Select a task to view its details, or select **See all Security Tasks** to view a complete list of Security Tasks. For details on Security Tasks, see Security Tasks.

Additional resources



Use the additional resources section on the edge of the screen to navigate to documentation and videos relevant to learning Security Center as well as information on managing instance security.

Security Event Notifications

View, manage, and analyze the default security event notification policies on your ServiceNow instance, as well as access the functionality to create custom policies.

Access Security Event Notifications from the Security Center homepage by opening the **Security Monitoring Console** in the **Security Consoles** section, then selecting the **Security Event Notifications** tab.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Customize and create notification policies that trigger email notifications when users perform actions in the ServiceNow AI Platform that might be insecure or require admin monitoring.

Admins can customize the values for the default policies, clone, and edit default policies or create their own custom ones.

Security policies

The Security Event Notifications console displays important information regarding the security policies on your instance. This table includes columns displaying:

Label	Description
Name	The name of the security event notification policy.
Status	The status of a policy can be either active or inactive.
Updated	The date and time of when the policy was last updated.
Updated by	The user that updated a policy.
Last triggered on	The date and time the policy last ran.
Triggered count last week	The number of triggers a policy generated the past 7 days.
Percentage change	The rate of change for weekly triggers, calculated as a percentage. **Note:** For example, if this policy triggers an average of 5 notifications a week and it triggered 10 times last week, that would be a percentage increase of 100%.

Select a policy on the table to view more detail, including an overview, settings, and notification history. Select the **New custom policy** button to create a custom policy tailored to your organization's use cases.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Manage security banner announcements

Select **Manage announcement settings** to control whether admins receive banner notifications on this instance. For information on these announcements, see Security banner announcements.

Create custom security event notification policies

Learn how to create custom security event notifications that are specific to your organization's needs. This enables you to monitor actions taken by users and groups on your instance and generate notifications for potential security risks.

Before you begin
Role required: admin

Procedure

1. Navigate to the Security Center app and select **Notifications**.
2. Select **New custom policy**.
3. Select one of the three event types that will trigger the start of the policy, and select **Create**.
4. Configure the policy.
   See Configure preferences for security event notification policies to learn how to configure your new custom security event notification policy.

Modify security event notification policies

Learn how to modify the settings of your security event notification policies.

Before you begin
Role required: admin

Procedure

1. Navigate to the Security Event **Notification** homepage and select any of the policies you want to modify.

   Note: You cannot modify the trigger or condition logic for default policies. To modify these settings, you must first duplicate the policy which can be done by selecting the down arrow next to **Update**, and then selecting **Duplicate**.

2. Select **policy settings** to change the settings.
3. Select **Update** to save your changes.
4. **Optional:** Select **deactivate** until you are ready to start triggering notifications.
5. **Optional:** Start triggering notifications by selecting **Activate**.
   See Configure preferences for security event notification policies to learn how to configure your new custom security event notification policy.

Configure preferences for security event notification policies

Discover how to customize security event notification policies in Security Center to align with your organization's specific needs.

Before you begin
Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task

The **Policy settings** page is where you can customize the settings for a security event notification policy. Here, you can adjust options related to when the policy runs, the conditional logic, and the notifications that are sent.

Procedure

1. In Security Center, select **Notifications**.
2. Under the Security policies table, select a security event notification policy that you want to configure.
   For example, **Send notification when high privileged role is granted**.
3. Select **Policy settings**.
4. Configure the policy settings.

Policy settings configuration options

Label	What to configure
When to run	**Trigger**: The event that starts the policy.
Conditions	The conditional logic and conditions to apply to your policies. ○ **Condition logic**: two options ▪ **All conditions must be met to trigger this policy**: all conditions need to be valid for the policy to send notifications. ▪ **Any of the conditions must be met to trigger this policy**: notifications will be sent if any one of the conditions is valid. ○ **Add Condition**: Select Add Condition and provide the appropriate values for it. You can remove a condition by selecting **Remove condition**.
Notifications	The email body and email recipients: ○ **Notification**: Select one of the predefined notification templates. See Create a custom email for security event notifications for more information. ○ **Add Notification**: Select Add Notification. ○ **Groups**: Select the group who should receive the notification. ○ **Users**: Select the users who should receive the notification. You can remove a notification by selecting **Remove notification**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note: If you want to make a policy inactive, select **Deactivate**. If you want to replicate a policy, select the down arrow next to the **Update** () button.

5. Select **Update** to save your settings.

Create a custom email for security event notifications

Learn how for creating a custom email for security event notifications by configuring new notifications, setting triggers, defining recipients, and crafting email content with dynamic event fields.

Before you begin

Role required: admin

Procedure

1. Select **system notifications** > **notification**.
2. Select **new**.
3. Enter a **name** for the notification field.
4. Select the field next to **table** and enter security policy notification (*sn_vsc_security_policy*).
5. Configure the new record.
   There are three tabs within the record that must be configured: **When to send**, **Who will receive**, and **What it will contain**.

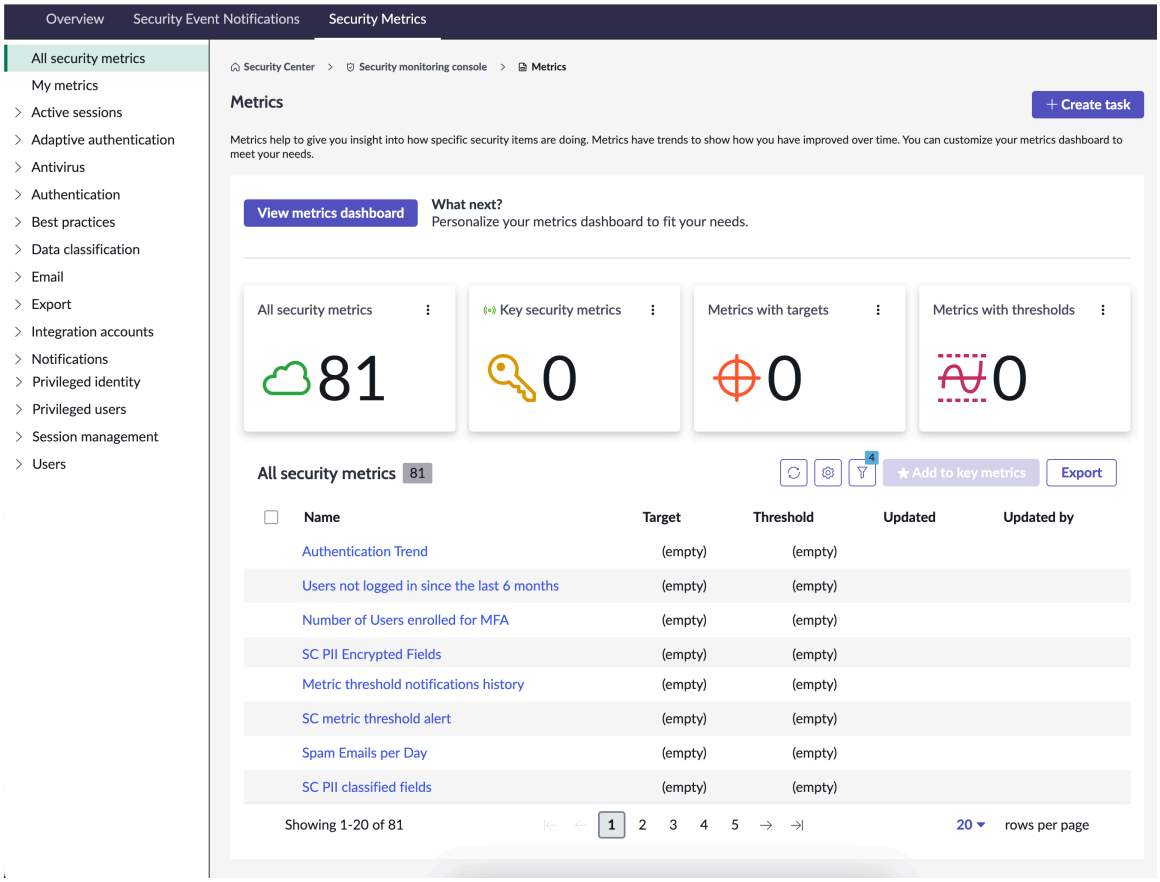
Tab	Description
When to send	Select the field next to **Send when** label and select **Triggered**.
Who will receive	○ Select the local icon next to **Users/Groups in fields**, and select both **Users** and **Groups**. Select the **Add Item** (>) icon to move the fields into the **Selected** text field. ○ Right click on the record header banner and select **Save**.)
What it will contain	Create an email template. See Create an email template for more information. Enter fields of the event into **Message HTML**. This can be done by using the `${event_id.FIELD_NAME}`. Here's an example: `Role: ${event_id.role.URI_REF} Granted to: ${event_id.granted_to.URI_REF}`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Tab	Description
	Granted by: ${event_id.user.URI_REF} Logged at: ${event_id.sys_created_on} Security Center Notification: ${execution.policy.name}

6. Select **Submit**.
7. Add a custom notification to email template in security event notifications.
   a. In Security Center, select **Notifications** > **Policy settings**.
   b. Navigate to the **Notifications** label.
   c. Enter the name of the custom notification you created in the **Notification** field.

Security Event Notifications history



Explore the complete history of security event notifications on your instance.

The **Notifications** page provides an overview of the notification history for all security event notification policies on your instance. You can view the data in charts, presenting it graphically and applying performance analytics functionalities like targets, thresholds, and KPI signals. Alternatively, you can view the data in a table format, enabling you to utilize standard functionalities such as search, sort, filter, and querying.

Security metrics

Monitor over 50 different Security Metrics to identify potential security threats or insecure behaviors. Set thresholds for email notifications, visualize, and analyze the data in multiple ways. Export the data, or create dashboards with the metrics that are most important to your organization.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

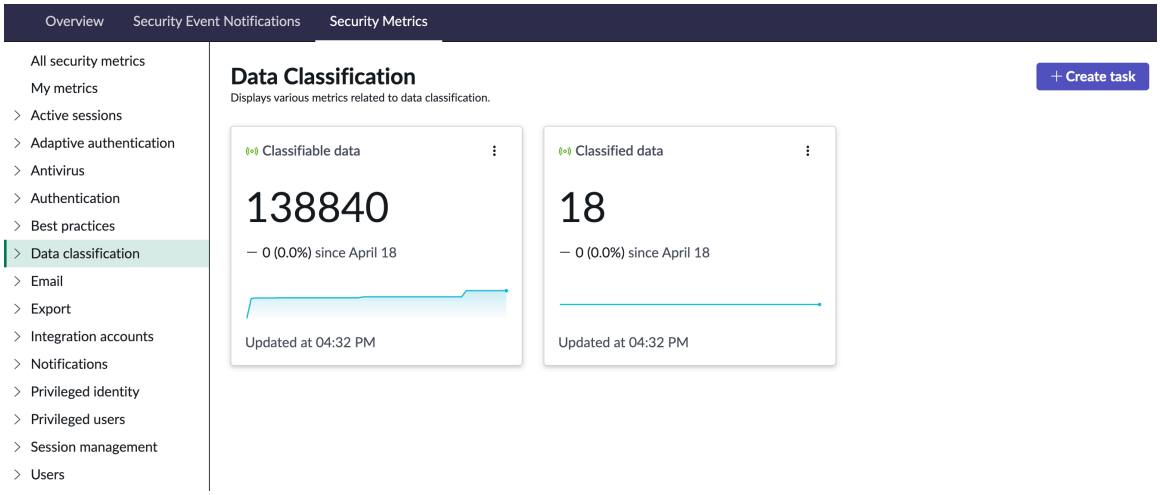
Access Security Metrics within Security Center by selecting **Security Monitoring** in the tools section. Then, select the **Security metrics** card.

All Security Metrics dashboard

View metrics such as failed logins, exports, impersonations, and more using this dashboard. The cards above the list provide a count of the metrics that match specific criteria listed on the card. Select any of these cards to filter the list to show only those metrics that match the criteria.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

My metrics dashboard

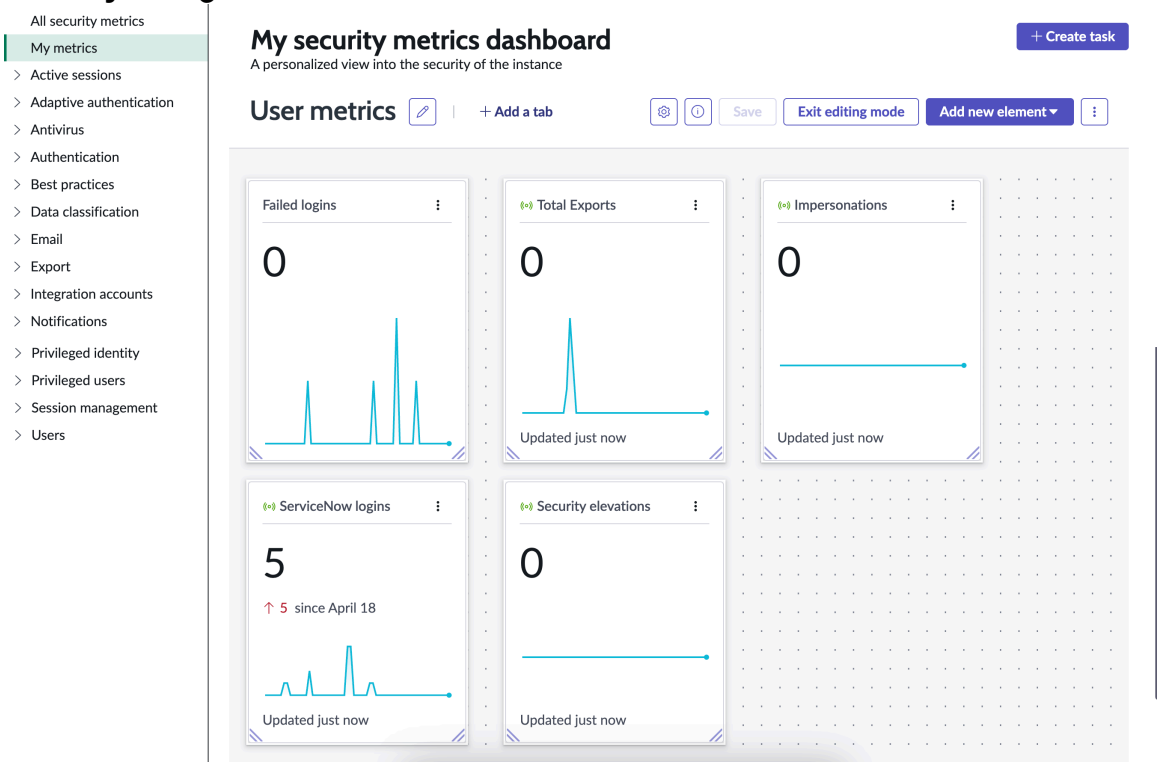


This is a customizable dashboard that displays information about metrics you care about most. Select **Edit** to customize your dashboard by adding visualizations, filters, headings, images, rich text, and lists. To learn about the various ways you can customize your dashboard, see Dashboards in Platform Analytics.

Metrics navigation pane

The navigation pane on the edge of the screen displays your instance metrics. Select **All Security Metrics** to view all metrics in a single list. Select any of the items under **All Security Metrics** the entry to browse the metrics organized by category.

Each category displays a dashboard similar to the security **My metrics dashboard**, with cards for the metrics in that category.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Customize the My security metrics dashboard

Discover the flexibility of the My security metrics dashboard, which can be customized with metrics from various sources like graphs and charts. Tailor the dashboard to suit your organization's specific requirements.

Before you begin

To customize the Security Metrics dashboard, confirm you are within the Security Center application scope. To switch to this scope, select **application picker** > **Application scope**, and type security center.

Role required: admin

About this task

Implement and customize My security metrics dashboard. Add metrics and content to your dashboard from a variety of sources, such as graphs and charts generated from a report. Learn the steps required to add a tab to your dashboard so that you can customize it to meet your organization's needs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Access Security Metrics within Security Center by selecting **Security Monitoring** in the tools section, and selecting the **Security metrics** card.
2. Enter edit mode by selecting **Edit**.
3. Create a tab by selecting **+Add a tab**.

   Note: You can also add a new tab by selecting the **plus (+)** icon next to an existing tab.

4. Edit the title of your newly created tab by selecting the pencil icon and entering a name.
5. Add an element to your tab by selecting **Add a new element**.
6. Select **Save**.
7. **Optional:** To share the dashboard with users, groups, and roles in your organization, select **More actions menu** > **Share**.
   a. Enter the name of a user to grant access to.
   b. Select **Confirm**.

Configure Security Metrics to send email when thresholds are triggered

Learn how to configure Security Metrics so that your instance generates an email notification when a threshold is triggered.

Before you begin

Role required: admin

Procedure

1. In the Security Center, navigate to **metrics**.
2. Select a metric that you want to set a threshold for in your organization.

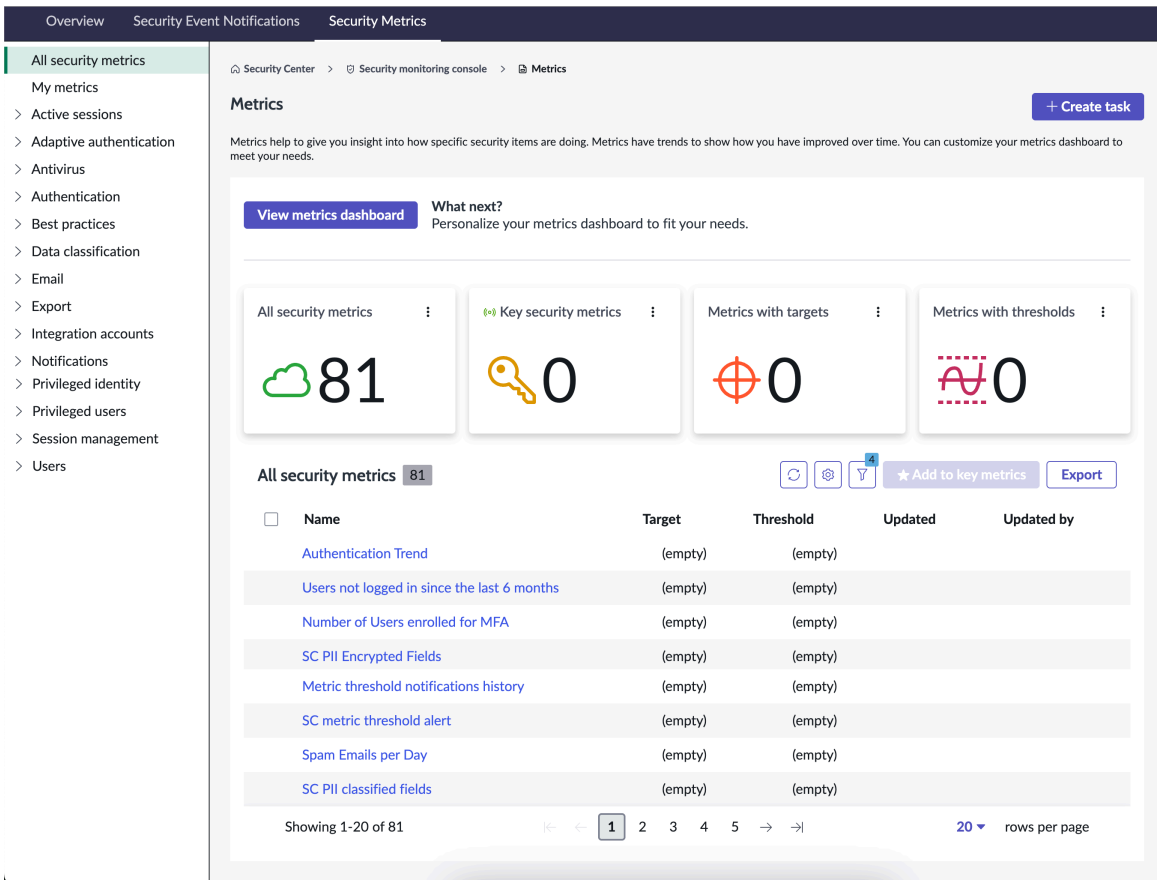
   Example
   To manage failed logins, you can set a threshold. When the number of failed logins reach this threshold, admins or security experts in your organization are notified. The appropriate Security Metric to target in this case is **users** > **failed logins**.
3. Select the **Thresholds** icon.
4. Select the **plus (+)** icon on the thresholds panel to configure the form.
   The options available are to set the visibility, threshold type, and threshold value.

   a. For visibility, select **for everyone** if you want everyone to receive the notification, or **for me** if you only want to receive a notification.

   b. In **threshold type**, select **all time high**.
   This field triggers the threshold notification.

   Note: A threshold value must only be entered when the **Threshold Type** is set to **Less than** or **More than**.

5. Select **save** to create the threshold.
   Next, the notification must be set up.
6. Select **all**, and enter **system notification**.
7. Navigate to **email** > **notifications**.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

8. In the **name** column, enter `*pa thre`.
   The threshold notifications are event-based, and they're set up in the PA Thresholds Notification table.
9. Select **PA Thresholds Notification**.
   There are three tabs in the results:
   - When to send: Specifies what must occur to send the email notification. In this example, once the threshold you previously set is reached, the email is triggered.
   - Who will receive: Specifies which users receive the notification. You can add users and groups.
   - What it will contain: Specifies the script action that a user can modify to customize the message that users and the group will receive. To learn more about creating script actions, see Script actions.

All Security Metrics

Navigate to **All Security Metrics** to view a table with the data related to the Security Metrics of your instance.

Access the list of all Security Metrics on a filterable list by accessing the Security Metrics Dashboard, and selecting the **All Security Metrics** option on from the list on the left.

Select any item on the list to view details on each metric.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Active Sessions

View the trend line of the active users on the ServiceNow AI Platform.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

This page displays cards with information on metrics related to active sessions. Each card displays a trend line for the following metrics:

- User sessions: Metrics related to active user sessions on your instance.
- Privileged user sessions: Metrics related to privileged users or those who have been assigned additional roles.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Adaptive authentication Security Metrics

Use authentication policies to evaluate authentication requests and deny or allow access to your instance based on the specified policy conditions.

Adaptive authentication metrics enable you to monitor how adaptive authentication is being used on your instance. View a summary of all of your metrics on Adaptive authentication, individual metrics such as policy result rates or denied IP addresses. This page requires the Adaptive Authentication (*com.snc.adaptive_authentication*) plugin for adaptive authentication to be available in your instance. You must enable Authentication Policy to see the metrics. See Activate adaptive authentication and Configure adaptive authentication properties for more details.

Note: This feature was released with version 1.2.

- Policy result rates: All the successful and failed adaptive authentication events.
- Event failure distribution: All the failed events for each event type.
- Event success distribution: The successful events associated with every event type.
- Denied IP addresses: The number of IP addresses blocked by the instance, along with their associated data.
- Authenticated user logins: The number of events counted for each event type, excluding the pre-login event.
- API user logins: The number of events associated with API Authentication policies for each event type.
- Authentication trend: The total number of events recorded.
- Authenticated users: The number of users counted for each event type, excluding the pre-login event.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Antivirus

Displays the trend of when events occur on potentially infected files. See when they are discovered, placed into quarantine, restored, or deleted.

This page displays cards with information on metrics related to antivirus activity on your instance. Each card displays a trend line for the following metrics:

- Quarantined files: The number of files that potentially contain malware.
- Downloaded files: The number of downloaded files.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Restored files: The number of files that have been restored.
- Deleted files: The number of deleted files.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Authentication

View trends for metrics related to authentication schemes, such as Multi-Factor Authentication(MFA) use, web service accounts, and biometric scanner usage.

This page displays cards with information on metrics related to authentication. Each card displays a trend line for the following metrics:

- Users enrolled for MFA
- Users using MFA
- High privileged non-MFA users
- Active MFA users
- Locked out MFA users
- Web service account only
- X509 certificates expiring in 30 days
- Biometric scanner/hardware key users
- REST API's Without Access Policy
- Integration Accounts without Web Service Access Only Flag enabled

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Data Classification

Access the Security Metrics for data classification on your ServiceNow instance.

Data classification enables you to apply data classification labels to existing dictionary entries in any table. These labels help to provide visibility into the types of data hosted in your instances. Use these classifications to comply with privacy laws, and meet industry regulation requirements.

See data classification for more information.

- **Classifiable data**: Tables or columns that can be classified.
- **Classified data**: Dictionary entries, tables, or columns that are classified.

The data is graphically displayed in a customizable chart that provides detailed analysis such as setting targets, thresholds, trends, statistics, or forecasts. The data is also organized as records in a table. See Analytics Hub for more information.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Authentication metrics

View metrics related to authentication on your instance from a dashboard.

This page displays cards with information on metrics related to authentication. Each card displays a trend line for the following metrics:

- Users enrolled for MFA: Total count of users enrolled to use MFA.
- Users using MFA bypass: Total count of users who are circumventing multi factor authentication.
- High privileged non-MFA user: Total count of high-privileged users that are not using MFA.
- Active MFA users: Total count of MFA users that are active on your instance.
- Locked out MFA users: Total count of MFA users who are locked out on your instance.
- Web service account user: Total count of users with web service account only.
- X509 certificates expiring: Total count of X509 certificates that are expiring in the next 30 days.
- Biometric scanner/Hardware key users: Total count of users login with biometric scanner or Hardware key.
- REST API's Without Access Policy: Total count of users login without REST API's Access Policy.
- Integration Accounts without Web Service Access Only Flag enabled: Total count of users login without Integration Accounts Web Service Access Only Flag enabled.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Email

Displays data related to spam emails that are being received externally.

The page displays a card displays a trend line for the spam emails, representing the number of junk mail received per day.

Select the card to view additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Export

Discover the data that is commonly exported, and which users do the exporting.

This page displays cards with information on metrics related to export. Each card displays a trend line for the following metrics:

- Total exports: Total count of table records exported by user.
- Classified exports: Total count of table records exported, summarized by the data classification assigned to them.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

© 2026 ServiceNow, Inc. All rights reserved.

Integration Accounts

View the trends about the integration accounts that are created on the ServiceNow AI Platform.

Security Center identifies integration accounts as user accounts with the **Internal integration user** field selected on the User [sys_user] record. These accounts are intended to manage integrations between your instance and external applications or systems. To view all integration accounts on your instance, navigate to **All** > **User Administration** > **Users** and filter by **Internal integration user = true**.

This page displays cards with information on metrics related to integration accounts that are created on the ServiceNow AI Platform. Each card displays a trend line for the following metrics:

- Total integration accounts: Trends related to integration accounts on your instance.
- Active integration accounts: Trends related to active integration accounts on your instance.
- Inactive integration accounts: Trends for the total count of integration accounts that are inactive on your instance.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Privileged Identity

Analyze data related to metrics for users with privileged identity.

This page displays cards with information on metrics related to privileged identity users and their activity on your instance. Each card displays a trend line for the following metrics:

- Admin logins: Total count of logins with users of the admin role.
- Impersonation: Total count of impersonations performed by users with the impersonator role.
- Elevation: Total count of security elevations performed by users with the security_admin role.
- ServiceNow logins: Total count of logins by ServiceNow employees.
- Admin users added: Total number of users given the admin role.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Privileged Users

View the trend line for the privileged users (active and inactive) and their activity on the ServiceNow AI Platform.

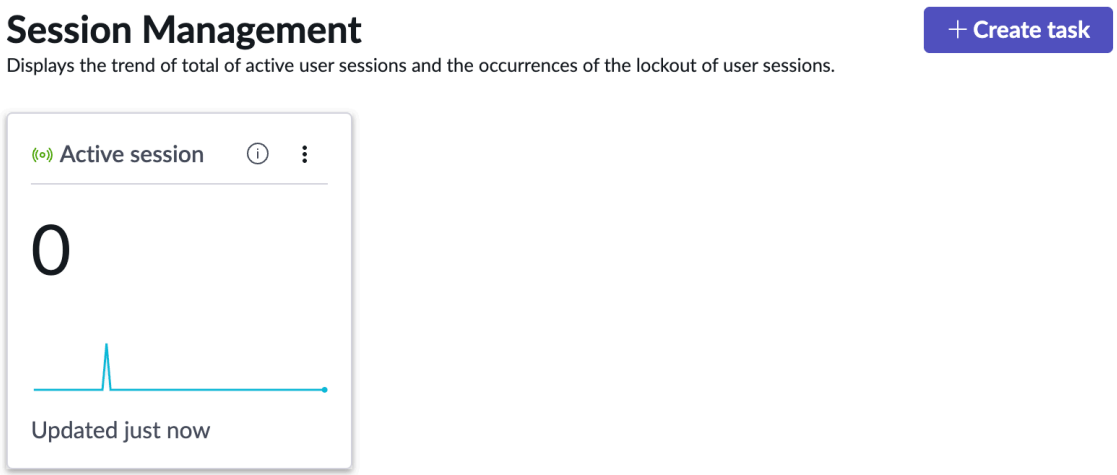
The Privileged users overview section displays the trend line for the privileged users (active and inactive) and their activity on the ServiceNow AI Platform. Privileged users are users who have been assigned additional roles by admins to access the features like High Security Settings, Import, and Portal users.

Below is an explanation of the privileged users:

- Total users: Total count of users on your instance.
- Active users: Total number of users who initiated sessions on your instance.
- Inactive users: Users who have not recently logged into your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

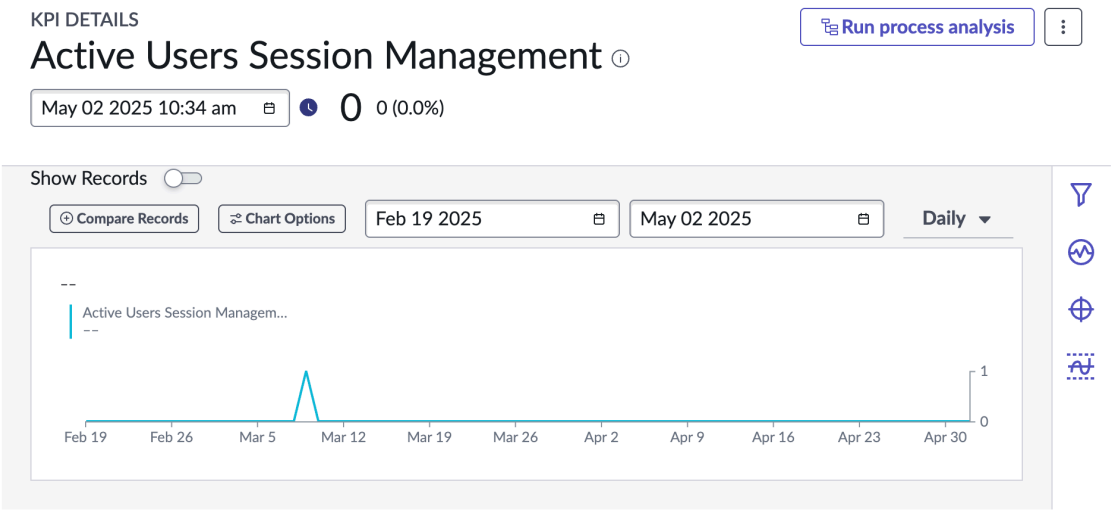
- Inactive users who are not locked out: Users who have not recently logged in but still have access to their account.
- Locked out users: Users who are not permitted to authenticate into their account.
- New users: Users who have recently been added to your instance.
- Successful logins: Users that have successfully logged in.
- Failed logins: Unsuccessful login attempts.
- Local logins not protected by MFA: Users that logged in without MFA.
- Users never logged in: Users that have never logged into your instance.
- Users not logged in since last month: Users that have not logged in the last 30 days.
- Users not logged in since the last 6 months: Users that have not logged in the last 6 months.
- Users not logged in since the last 1 year: Users that have not logged in the past year.
- Need to reset password: Users that need to reset their password.
- Password reset failures of the users: Number of password failures per user.



Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Session management



View metrics related to user sessions and the frequency of lockouts of the sessions.

The page displays a card displays a trend line for active sessions, representing the number of active sessions on your instance.

Select the card to view additional details.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

From the details page, you can use the buttons on the edge of the screen to configure filters, KPI signals, targets, and thresholds.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

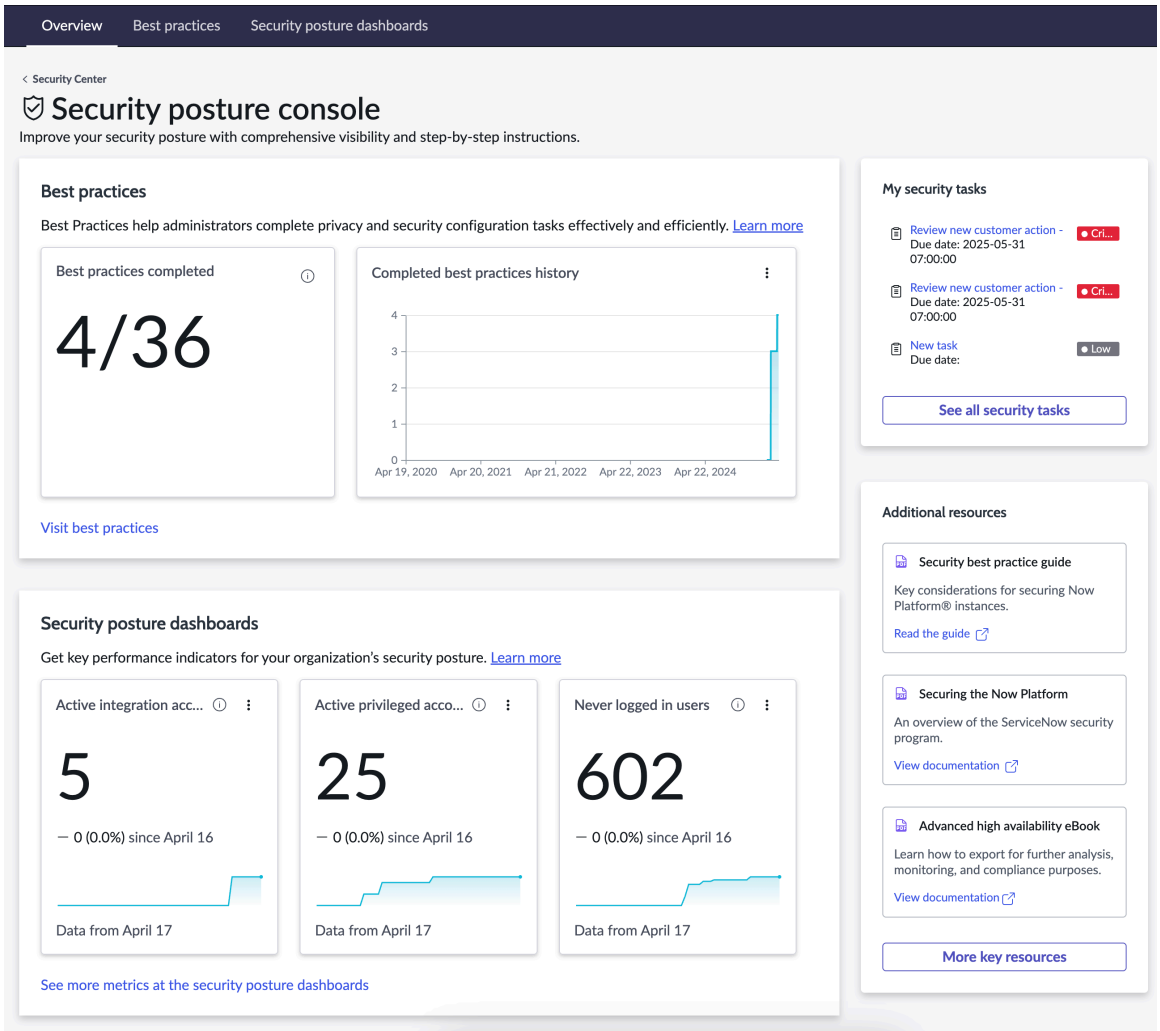
Users

View the trend line for total users (active and inactive) and their activity on the ServiceNow AI Platform.

The Users overview section displays the trend line for total users (active and inactive) and their activity on the ServiceNow AI Platform.

Below is an explanation of the type of users:

- Total users: Total count of users on your instance.
- Active users: Total number of users who initiated sessions on your instance.
- Inactive users: Users who have not recently logged into your instance.
- Inactive users who are not locked out: Users who have not recently logged in but still have access to their account.
- New users: Users who have recently been added to your instance.
- Successful logins: Users that have successfully logged in.
- Failed logins: Unsuccessful login attempts.
- External logins: Authentications that uses a 3rd party.
- Local logins not protected by MFA: Logins that do not use MFA.
- Users not logged in since last month: Users that have not logged in the last 30 days.
- Users not logged in since the last 6 months: Users that have not logged in the last 6 months.
- Users not logged in since the last 1 year: Users that have not logged in the past year.
- Need to reset password: Users that need to reset their password.
- Password reset failures of the users: Number of password failures per user.



Select the card to view additional details.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Security posture console

Improve your ability to identify, respond to, and recover from security threats with comprehensive visibility and step-by-step instructions.

The security posture console is divided into sections to provide information about best practices and security posture dashboards. Find additional details by selecting any of the cards in these sections. You can also use the bar at the top of the page to navigate between this page and the best practices and security posture dashboards section of Security Center.

Best Practices

This section displays the count of best practices, and how many you have applied to your instance. You can see a chart showing your completed best practices over time.

Security posture dashboards

This section displays the number of active integration accounts, active privileged accounts, and users that have never logged in.

Active integration accounts

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Integration accounts are user accounts that manage integrations between your instance and third party applications.

Active privileged accounts

Privileged users are users who have been assigned additional roles by admins to access the features like High Security Settings, Import, and Portal users.

Never logged-in users

User accounts that have never logged in to your instance.

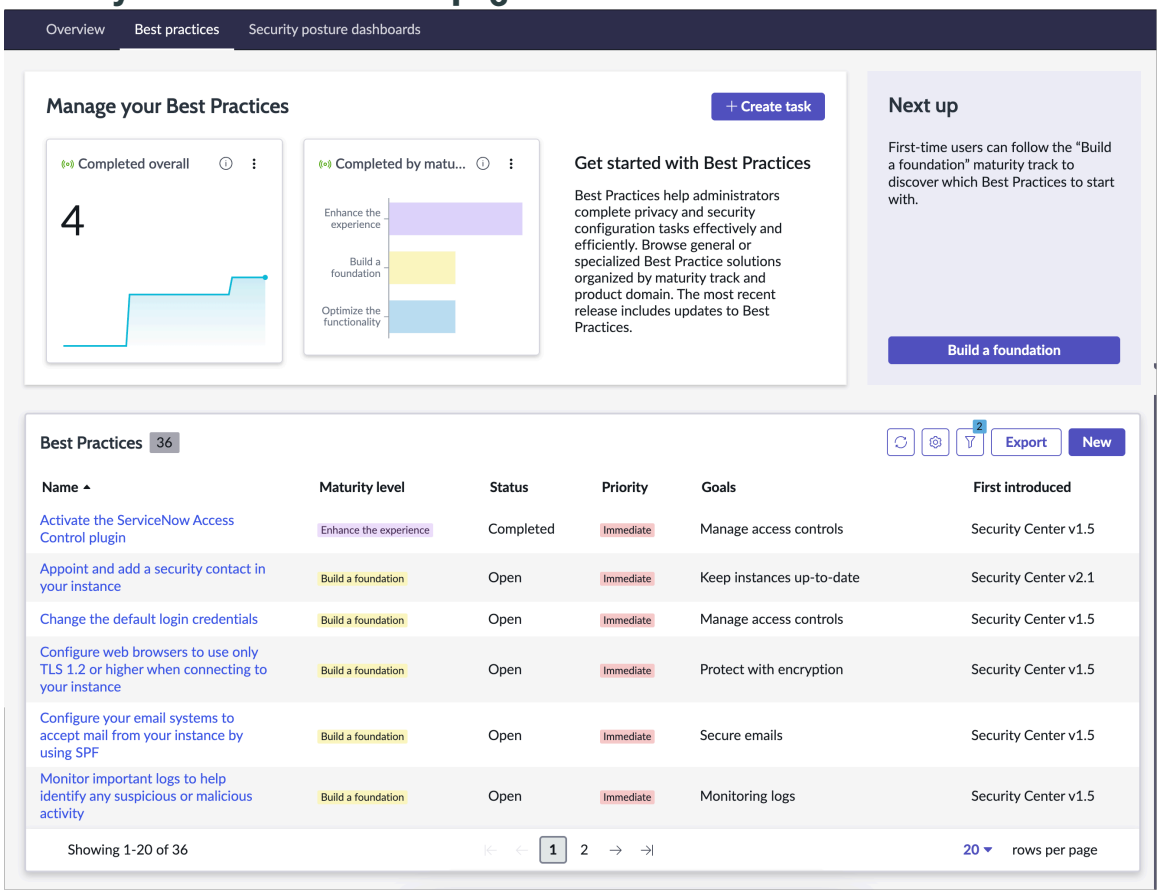
My Security Tasks

View the most urgent Security Tasks assigned to you. Select a task to view its details, or select **See all Security Tasks** to view a complete list of Security Tasks.

Additional resources

Use the additional resources section on the edge of the screen to navigate to documentation and videos relevant to learning Security Center as well as information on managing instance security.

Security Best Practices



Use Security Best Practices to implement privacy and security configuration tasks on your ServiceNow instance.

Identify best practices to improve your security posture, and follow step-by-step instructions on how to implement them. Security Best Practices provide the following:

- The home page shows an overview of your progress on implementing security best practices. You can also organize and manage lists of security best practices according to your organization's goals.
- The overview page provides details of each security best practice, the steps to implement them, and a record of all activities and comments.
- The task steps page provides you with instructions on how to implement security best practices.
- The activity page tracks the history of the user and system actions related to your security best practices.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Security Best Practices home page

The home page displays a **Manage your best practices** section, which includes graphs provide an overview of your progress.

Completed overall

Displays a count and trend line of best practices you have completed. Select the card to view the **Completed Overall** metric page in Security metrics.

Completed by maturity level

Displays a chart of completed best practices organized by maturity level (see a description of maturity levels in the proceeding table). Select the card to view the **Completed by Maturity Level** metric page in Security metrics.

Build a foundation

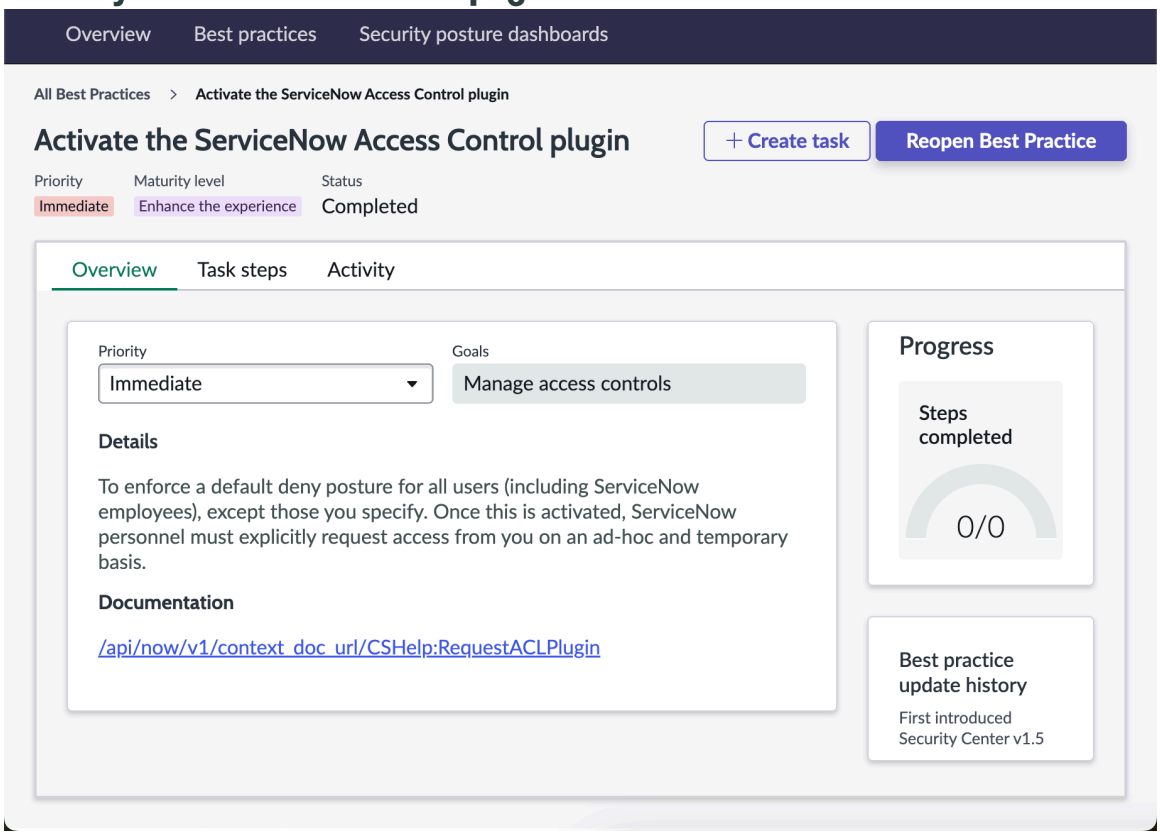
Select the **Build a foundation** button to filter the table on this page to display only best practices in the **Build a foundation** maturity level. These are lower impact changes you can make to start improving instance security.

Create a task

Use the **+Create task** button to create a Security Task to track or delegate best practice work. For details on Security Tasks, see Security Tasks.

The table enables you to apply filters so that you can sort and save filtered lists, which you can use as work lists for different use cases or roles. See save a filtered list for more information.

The following are explanations of the fields related to the security best practices table.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Summary of fields used in the security best practices table

Name	Description
Name	Word used to identify a security best practice.
Maturity level	Applications and features that have been arranged by the order of impact to provide you measurable results. The values for maturity levels are: • Build a foundation • Enhance the experience • Optimize the functionality • Add advanced features These can also be thought of as crawl, walk, run, and fly phases.
Status	Current state of a best practice: • Open • In progress • Completed
Priority	Order of importance for implementing a best practice in your organization: • Immediate • Later • Not applicable
Goals	Security category that a best practice addresses: • Address initial security configurations • Secure emails • Monitoring logs • Manage access controls • Protect with encryption • Keep instances up to date
First introduced	Which Security Center version the best practice was introduced.
Changed	Which Security Center version the best practice was changed.
Removed	Which Security Center version the best practice was removed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Security Best Practices details page

Select a best practice from the table to view its page. At the top of the details page, you can view general information about the security best practice including priority, maturity level, and status. Use **Complete Best Practice** button to mark a the practice as complete, or **Reopen Best Practice** button to mark the practice complete. Use the **+Create Task** to create a Security Task to track and delegate this task. For details on Security Tasks, see Security Tasks.

This page provides more information on the best practice, divided into tabs:

Overview

This tab contains the **Priority** drop-down menu, which enables you to specify the security best practices that are important to you at this time and which are not applicable.

The details section provides content about the features associated with the security best practice, and the documentation section provides one or more links where you can find additional information.

The **Progress** card on the right shows the number of steps completed versus the total number of steps included. Select **go to next step** to navigate to the next incomplete step.

The **best practice update history** card provides a snapshot of the release information for the best practice. You can track which ServiceNow Security Center version the security best practice was released in, and which versions it was subsequently last updated in.

Task Steps

This tab provides step-by-step instructions for how to implement this security best practice. See complete a security best practice for more information.

Activity

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

This tabe displays timestamped activities listed from newest to oldest. Use search and filter to query for information. See apply filters to the security best practices table for more information.

Complete a security best practice

Learn how to complete a security best practice on your ServiceNow instance.

Before you begin

Role required: admin

About this task

Complete the following steps to implement security best practices on your ServiceNow instance.

Procedure

1. Access Security Best Practices by selecting **All** on your ServiceNow instance and then entering **best practice**.
2. Apply a filter to view security best practices to implement.
   a. Navigate to the **Best Practices** table in the UI.
   b. Select the kebab menu, or the item with three vertical dots (⋮) in the **Status** column.
   c. Select the **Open** and **In progress** options, and then select **apply**.
3. Select the name of a security best practice to implement.
4. Select **Go to next step**.
5. Select a task step from the **task steps** list.
6. Select the caret down (v) icon to view the implementation instructions for that step.
7. Read the instructions and then implement them on your ServiceNow instance.
8. Select **Mark step complete** when you're done with the task.

   Note: You can skip the task if you want to come back to it later, or if it doesn't apply to your organization's goals. In addition, you can reopen a completed task step by selecting the task step, and then selecting **Restart step**.

9. Select **Complete Best Practice**.

   You can complete a security best practice at any time. You don't have to complete all the steps and it's ok if you skip them. However, consider inserting a comment in the Activity subtab when completing a security best practice when you have not completed all the steps for an audit reference.

View activity of a best practice

Track the chronological and timestamped history related to a security best practice that you're completing on your ServiceNow instance, along with the user that initiated the activity.

Before you begin

Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Access Security Best Practices Manager by selecting **All** on your ServiceNow instance and then enter best practice.
2. On the Best Practices table, select a security best practice you want to view the activity for in the **Name** column.
3. Select the **Activity** tab.

   Examples of activity that you can view includes field changes such as if the status of a security best practice has changed from Open to Complete, or when a task step is completed or skipped. In addition, you can enter additional information related to an activity by entering in a comment in the text box.

View data of completed best practices

See visual representations of the total amount of best practices completed, or segmented by maturity level.

Before you begin
Role required: admin

About this task
Complete the actions to see charts that provide visual trends of security best practices that were completed overall, and by maturity level.

Procedure

1. Access the Security Center app and navigate to the **Best Practices** tab.
2. Under the **Manage your Best Practices** card select the **Completed overall** chart.
3. View the chart to see trends regarding security best practices configurations that were completed.
4. Select **Completed by maturity level** to see a chart, which displays trends of best practices completed by maturity level.

Filters the security best practices table

Apply filters to return more relevant results for your security best practices.

Before you begin
Role required: admin

Procedure

1. Access Security Best Practices Manager by selecting **All** on your ServiceNow instance and entering best practice.
2. Navigate to the **Best Practices** table and select a field you want to apply a filter to by selecting its kebab menu, or the one with three vertical dots (⋮).

Fields	Filter
Name	Combine a conditional operator with a string of text to return security best practices that match the name you entered.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Fields	Filter
Maturity level	Apply a filter to return security best practices that match one or more of the following maturi ty levels: ○ Build a foundation ○ Enhance the experience ○ Optimize the functionality ○ Add advanced features
Status	Apply a filter to return security best practices that match one or more of the following status es: ○ Empty ○ Open ○ In progress ○ Completed
Priority	Apply a filter to return security best practices that match the following priorities: ○ Empty ○ Immediate ○ Later ○ Not applicable
Goals	Apply a filter to return security best practices that match one or more of the following goals: ○ Address initial security configurations ○ Keep instances up to date ○ Manage access controls ○ Monitoring logs ○ Protect with encryption ○ Secure emails **Note**: Advanced filters are applied for goals by default. To modify them, select **Make changes** > **Advanced view** > **Select field goals** and then build the rest of the condi tions and select **Update**.
First introduced	Combine a conditional operator with a string of text to return best practices that were first introduced with the version you entered.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Fields	Filter
Changed	Combine a conditional operator with a string of text to return security best practices that changed in the version you entered.
Removed	Combine a conditional operator with a string of text to return security best practices that were removed in the version you entered.

Save a filter for future use

Discover the steps for saving filters in your security best practices for later reuse.

Before you begin
Role required: none

About this task
After you create filters in the security best practices table, you can save them for use the next time you authenticate into your instance. If you want more flexibility on the type of filters you can create, you can apply an advanced filter.

Procedure

1. Select the Show filter ( ) panel icon.
2. In the **Filter** dialog panel, scroll down and select **Advanced view**.
3. Build a filter by adding conditions that contain a field, operator, and values.
4. Select **Save filter**
5. Enter the Filter name.
6. Select a permission.
7. Select **Save**.
8. Select **Update** to apply the saved filter to the security best practices table.

Use a saved filter

Discover the steps for using the filters that you saved for your security best practices.

Before you begin
Role required: none

About this task
After you log out of your instance your filters are reset to the default settings. The following steps show how to retrieve a saved filter so that you can reapply it on the security best practices table.

Procedure

1. Select the Show filter panel ( ) icon.
2. In the Filter dialog box, scroll down and select **Advanced view**.
3. Select **Use existing filter**, and then select a saved filter from the dropdown list.
4. Select **Update** to apply the saved filter.

Best Practices

Learn details about the Best Practices in the Security Posture Console.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
Activate the ServiceNow Access Control plugin	Use the ServiceNow Access Control plugin to control which employees can access your instance, and when. Enforcing a default deny posture for all users except those users you specify. This can include ServiceNow employees. Using this plugin helps prevent unwanted access to your instance. **Note:** After ServiceNow Access Control is activated, personnel must explicitly request access from you on an ad-hoc and temporary basis. For details on this plugin, see ServiceNow access control.
Appoint and add a security contact in your instance	Select an information security contact within your organization who receives security-related information from the Security Team. This contact is in addition to your admin, who also receives these updates. This information could be security issues, security alerts, or details about important software updates. For details on adding a security contact, see KB0621516.
Change the default login credentials	Change the passwords on your instance's built-in user accounts, such as admin, ITIL, and employee. These accounts are provisioned with default passwords, unique to your instance, but should be changed as soon as possible. For details on how to change the passwords for user accounts on your instance, see Configure password for a user.
Configure web browsers to use only TLS 1.2 or higher when connecting to your instance	Verify that browsers that connect to your instance are using the more secure Transport Layer Security (TLS) 1.2. This change can be made on the browser or enforced by your web proxy or other gateway. Consult the documentation for your browser, web proxy, or gateway for steps on how to configure those products to use only TLS 1.2.
Configure your email systems to accept mail from your instance by using SPF	If your organization uses Sender Policy Framework (SPF) to control inbound email with anti-spam technology, you must configure it to accept email originating from your instance. Configure SPF to query the SPF records dynamically. If SPF isn't an option, another approach is to add the mail server IP addresses to your allow list. This configuration must be monitored as the addresses could be subject to change. For steps and additional details on these solutions, see KB0535456

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
Consider limiting file attachments, uploads, and downloads	Restrict attachment uploads by role, file extension, MIME type, or size to help prevent potentially malicious files being stored and delivered from your instance. You can also control which file types can be downloaded, including by MIME type, and prevent image access by unauthenticated users. These attachment restrictions are controlled by system properties on your instance. For details on their configuration, see Configure attachment system properties.
Disable browser SQL messages	Prevent SQL error messages from being presented in the web browser. Though useful to users and developers, these messages can be used by attackers to learn information about your system or to help guide their attempts to access your data. These messages can be turned off using a system property. For details on this system property, see Disable SQL error messages.
Disable password-less authentication	Help ensure strong authentication by disabling password-less authentication when possible. Without disabling password-less authentication, potential attackers could gain access to your instance by correctly guessing a user name (such as firstname.lastname or a role title). You can disable password-less authentication on your instance using a system property. For details on this property see .
Enable table auditing for important or sensitive data	Track changes to your data using table auditing. Auditing tracks the creation, update, and deletion of all records in the table where it's enabled, enabling admins to track changes to important or sensitive data. Admins can also choose to select specific fields in a table for auditing to see more targeted results or to reduce performance impact. For details on auditing on instances, see Auditing. For specific instructions on enabling auditing on a table, see Configuring auditing for a table.
Encrypt data at rest within the instance	Encrypt your data to maintain its confidentiality and integrity. Data on your instance can be within the database. You can also elect to subscribe to functionality to encrypt the data volume transparently on the backend. The physical disks on which the instance runs can also be encrypted in their entirety to guard data in case of their loss or theft. You can use different methods of encryption simultaneously for data stored in your instance, depending on your use case and the risks you wish to mitigate. For example, you

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
	can choose to transparently encrypt your data at rest using database encryption on most tables, cloud encryption on the entire data volume. You could also use full disk hardware encryption, which also requires a dedicated environment to protect against drive or server theft. Review the encryption options available with in Key Management Framework.
Enforce the use of strong passphrases	Use password policies to enforce the length, complexity, expiration, uniqueness, lockout, and more for native and local accounts on your instance. Use these policies to maximize security, encourage the adoption of long passphrases and help to eliminate the use of simple passwords. You can retain your existing policies for any external authentication services you have integrated, such as LDAP or SAML. For details on password policy configuration, see Configure your password policy.
Ensure automatic account creation	Use this feature to create user accounts by email dynamically. Activate this feature only if necessary for your business needs, only after you have defined a list of trusted domains from which accounts can be created. You can also control how passwords are assigned to new accounts created this way. For details on automatic user creation, see Enable automatic user creation.
Ensure Secure Access to knowledge bases	Manage access to knowledge bases and articles to help ensure secure and efficient information sharing. You can determine whether certain users or categories of users can access knowledge bases and knowledge articles by controlling contribute and read access. The specific configuration depends on your business needs. Learn about your options for configuring knowledge access at Managing access to knowledge bases and knowledge articles.
Ensure that the High Security plugin is installed and activated	Use the High Security plugin (HSP) to enhance security management and applying appropriate settings. High Security Settings provides a central location for security settings, creates a distinct security administrator role, a default deny property, and other important security features. HSP is installed and enabled by default on all new instances. You can request HSP activation for older instances, including instances that have had upgrades from an older version. Enabling HSP should be done only after careful testing in a

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
	non-production environment, as activation changes some fundamental properties and behaviors. For more details on the High Security plugin, see Enable High Security plugin.
Familiarize yourself with NOW security resources	Security information constantly evolves, so it's crucial to stay updated with security resources to keep your information security strong. Use the following resources to stay informed about security resources: • CORE Directory: ServiceNow CORE Compliance Portal • Securing the ServiceNow AI Platform: How ServiceNow protects customer data • Secure your instance
Harden your Instance	Use the Security Center Hardening tool to reduce risk by limiting weaknesses that could be exploited, and implement recommended settings to secure your instance further. Learn more about Security Center at Security Center. Review the available hardening settings at Hardening settings.
Install patches as soon as possible	Install patches and platform updates as soon as possible help ensure the highest levels of security for both your instance and those of other customers. Keeping current with updates also enables you to maintain continuous support by conforming to the EOL policy. Use Upgrade Center to help manage the process. Security fixes are routinely released for the Now Platform via the patches and hot fixes that accompany product feature updates. Upgrading when new patches and hot fixes are available helps reduce the risk of potential vulnerabilities. Information about Now Platform releases, patches, and hot fixes can be found in the Release Notes section of the product documentation. For more information, see Phase 1 - .
Integrate with MFA	Integrate third-party multi-factor authentication (MFA) with your existing SAML IdP to provide additional login security. MFA provides a high level of security because authentication requires multiple authentication factors. Something the user knows (the password) as well as something they own (a one-time code, mobile phone, or biometric attributes, such as a fingerprint).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
	Learn more about MFA integration at Multi-factor authentication.
Limit accepted email sender domains	Control which domains and users your instance can communicate with via email by using system address filters. These filters can be customized to your requirements. Learn how to configure trusted domains at .
Monitor important logs to help identify any suspicious or malicious activity	The system logs module provides a variety of logs that you can use to troubleshoot and debug transactions and events that take place within the instance. **Event logs** Event logs reveal much about system activity, including login events (successful or otherwise), and privilege escalation. **System logs** System logs contain extensive information about general activity, including configuration changes, system errors, workflows, and inbound / outbound data connections. **Note:** The Event and System logs can also be used to provide an audit trail of any activity by personnel. **Transaction logs** Transaction logs record all web browser-related activity for an instance and can provide details of every request made. Transaction logs can be useful for identifying unusual or malicious activity. **Table auditing and record history** Enable auditing for database tables. Record history is perpetual and enables you to track and view details of any changes made to the data since its creation. By default, only the incident, problem, and change tables are tracked. For other tables, auditing must be enabled manually. **Import logs** You can view detailed information related to data import activity into your instance by checking the import logs. These logs include information about source and status, time, and so on **Outbound web services logs** These show REST and SOAP request activity and can help you to track the volume and destination of connections to external services. Learn more about system logs in System logs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
Monitor login failure rates and create alerts	Monitor for unusual activity such as high numbers of failed logins, especially within short time frames. You can create alerts to send emails when a threshold you define is exceeded. Learn how to configure these thresholds at Indicator thresholds.
Monitor security events	Review the **My security metrics dashboard** to see the available security metrics for your instance, and set thresholds to generate email notifications for notable activity. Examples of notable activity can include: **Privilege escalation** Unexpected modifications made to privileged roles, such as Admin, ITIL_Admin, or any other roles with higher privileges could indicate suspicious actions. **Failed logins** Unusual numbers or patterns of failed logins can reveal potential brute force attempts or password spray attacks. **Admins and high privilege users added** New admin account creation should be checked for validity to help to prevent attempts at unauthorized privileged access.
Monitor your instance's Hardening Compliance level	Ensure that your instances are in compliance with the latest security hardening metrics using the Hardening tool in Security Center. Access this tool in a non-production instance assess impact to your environment. Ideally, the score should be as close to 100% as possible with a minimum score of 83%, without affecting product functionality. Learn more about Security Center's hardening settings tool at Hardening settings.
Refer your developers to the Secure Coding Guide	Help to ensure that your instance is secure and resistant to unauthorized access as possible using secure coding practices. The ServiceNow Secure Coding guide for Instance developers provides an overview of application security-related GlideScriptable classes and methods offered by ServiceNow. This guide is designed to assist and educate developers while creating and modifying the code on the target Instance. Review the guide at ServiceNow Secure Coding guide for Instance developers.
Remove the 'Remember Me' check box	Help prevent unwanted access to your instance by deactivating the **Remember Me** feature. When active, this feature stores a cookie is on the user's computer, which automatically authenticates the user on subsequent visits.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
	This can present security issues if users access your instance from an insecure endpoint, such as a shared computer. Learn more about this feature, and how to deactivate it in Remember me.
Restrict access to your instance from unknown IP addresses	Help prevent unauthorized access to your instance by restricting access from IP addresses unrelated to your organization. Anyone trying to access the instance from an unauthorized IP address are denied. If using this approach, consider allowing only your gateway or web proxy external addresses, as well as addresses from which your users access the instance from, including remote users. You can restrict both outbound and inbound access by IP address. Learn how to restrict access to your instance by IP address in Restrict access to specific IP ranges plugin.
Review ServiceNow's guidance on password spray attacks	Protect your instance against password spray attacks. These attacks attempt to gain access by testing a commonly used password against multiple accounts in succession. Learn more about spray attacks, and how to protect your instances from them in Password Spray Attack Mitigating Strategies.
Review the Shared Security Model	Understand your shared role as a customer in maintaining the security of your instances by reviewing the Shared Responsibility Model. The Shared Responsibility Model defines the partnership between and the customer, both with specific responsibilities. Learn more at ServiceNow Shared Responsibility Model.
Transfer log data from the instance for archival and reference	Archive your log data to retain it beyond the default 21-day log rotation period. This archival can be achieved using web services requests, the data export feature, the MID Server, or the Log Export Service from the Vault package. Use the following resources to learn more about these methods: • Web services • Exploring Log Export Service (LES)
Use encryption modules with RBAC to further enhance data access control	Learn how to use the Key Management Framework (KMF) to protect the data on your instance using Role-Based Access Control (RBAC). KMF uses cryptographic modules, which enable you to define what data on your instance is encrypted, and what method of encryption to use. Using

© 2026 ServiceNow, Inc. All rights reserved.

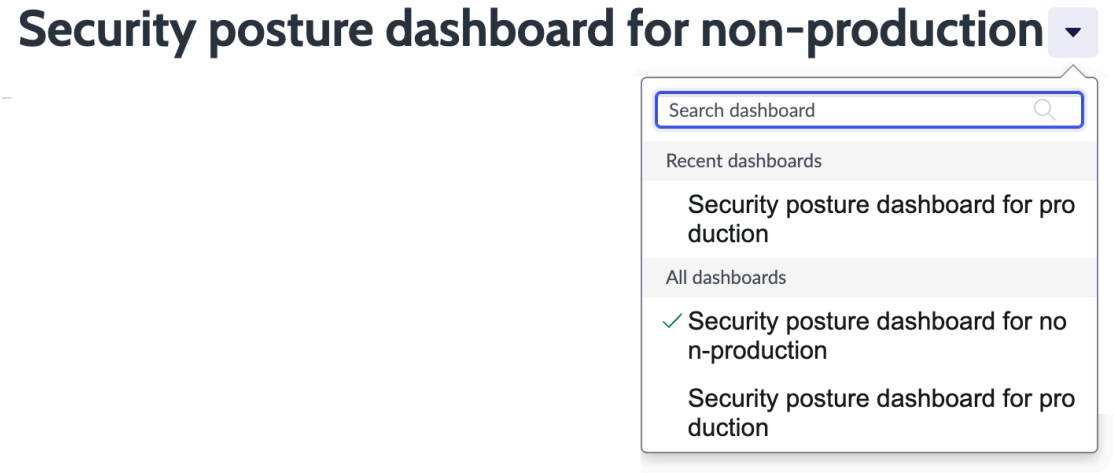
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
	multiple modules, you can encrypt different areas of your instance with different specifications. Learn how KMF and its components are used to encrypt your data at Exploring the Key Management Framework. Learn about cryptographic modules in Cryptographic module overview.
Use of certificate-based authentication with integration providers	Configure traffic to your integration providers using REST/SOAP connections to use certificate-based authentication. Secure Socket Layer (SSL) certificate authentication encrypts data in transit, helping to prevent it from being read as it is sent. Learn more about this configuration in Configure mutual authentication.
Use SAML authentication	Integrate third-party multi-factor authentication (MFA) with your existing SAML IdP to provide additional login security. MFA provides a high level of security because authentication requires multiple authentication factors. Something the user knows (the password) as well as something they own (a one-time code produced by an MFA token or mobile phone, or biometric attributes, such as a fingerprint). ServiceNow supports direct MFA integration with local accounts, LDAP, SSO with SAML, OIDC, or Digest. Adaptive Authentication is a prerequisite for SSO with MFA. MFA can be enabled for specified users and specified roles, and configured for ease of use. For example you can exempt recognized devices for a number of hours. You can view metrics for MFA use in the Security Center. Learn more about SAML authentication using these resources: • SAML 2.0 concepts • SAML 2.0 configuration using Multi-Provider SSO
Use the email filters feature set to deal with suspect inbound messages	Create email filters to filter out messages marked as suspicious by ServiceNow Antivirus Protection. In addition to virus protection, Antivirus Protection analyzes email for malware and SPAM, scoring and the results adding this information to the message in x-headers. You can use these headers as criteria for the Email Filters Plugin to act on if desired. Learn more about ServiceNow's antivirus feature at Antivirus Scanning.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

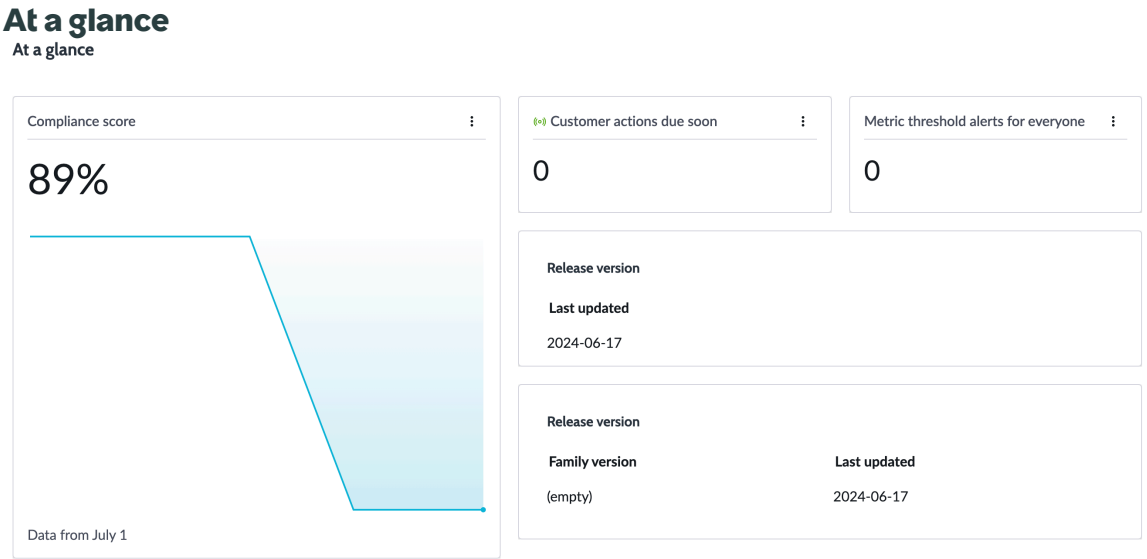
Best Practice	Description
	Learn how to configure email filters on your instance at Email filters.
Use the Syslog Probe to send logs to your SIEM	Use the ServiceNow syslog probe to send log messages from your instance to a Security Information and Event Manager (SIEM). An SIEM is third-party software or service that can be used for activity monitoring and identifying security events. Learn more about ServiceNow syslog probe configuration at Syslog probe.
Use your own mature email security environment	Consider using your own (or third-party) infrastructure to send and receive instance-related email and benefit from more precise perimeter email control. By using your own SMTP, POP3, or IMAP servers, you can control how mail is filtered and received before being sent to your instance. **Note:** Configuration of your own email infrastructure is considered an advanced email configuration, and can optionally use a third-party email infrastructure via OAuth 2.0 email authentication. See your own email vendor documentation and instructions for details.
Validate access using Access Analyzer	Use the ServiceNow Access Analyzer tool to help you compare and analyze permissions for selected users, roles, or groups. You can use this information to troubleshoot access issues, identify who has access to your sensitive data, and determine the correct level of access for users on your instance. Learn more about the benefits of Access Analyzer at Exploring Access Analyzer.

Security posture dashboards



Use the customizable single and multi-instance security posture dashboards to monitor your security KPIs. These dashboards consolidate the important information regarding the security of your instances in a single location and include a number of base system dashboard widgets.

Accessing the Security posture dashboards



To access the Security posture dashboard, open Security Center by navigating to **All** > **Security Center**. Select **Security posture console** in the **Security consoles** section. On the **Security posture console** page, select **Security posture dashboards** at the top.

Use the down arrow next to **Security posture dashboard** to switch between instance dashboards.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The dashboard is divided into multiple sections containing widgets related to an aspect of instance security. Select any widget on the dashboard to view more detail on this aspect of your instance's security.

The **At a glance** section displays an overview of security on an instance, such as a compliance score, Customer Actions due, and release information for the instance.

Compliance score

Displays your instance compliance score percentage over time, beginning with the date sown at the bottom of the widget. Select this widget to navigate to the Hardening compliance score trend.

Metric threshold alerts for me

Displays a count of Metric threshold event [n_vsc_metric_threshold_event] records assigned to the current user. Select this widget to navigate to a list of these records.

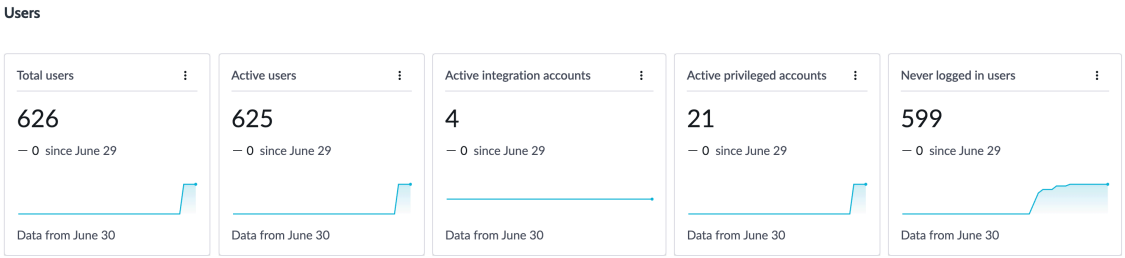
Metric threshold alerts for everyone.

Displays a count of unassigned Metric threshold event [n_vsc_metric_threshold_event] records. Select this widget to navigate to a list of these records.

Customer actions due soon

Displays a count of customer actions due soon. Select this widget to navigate to Customer Actions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Antivirus downloaded files

Displays a count of files uploaded to your instance that have been quarantined. Select this widget to view these quarantined files in the Antivirus section of Security metrics.

Release version

Displays the family version of the instance and the date of the last instance update.

Users

The **Users** section provides information on the users in your instance. The widgets on this section show user information, and a line graph showing changes to this information over time. Select a widget to view more detail.

Total users

Displays a count of users on your Users [sys_user] table. Select this widget to see details on these records in the Active Sessions section of Security metrics.

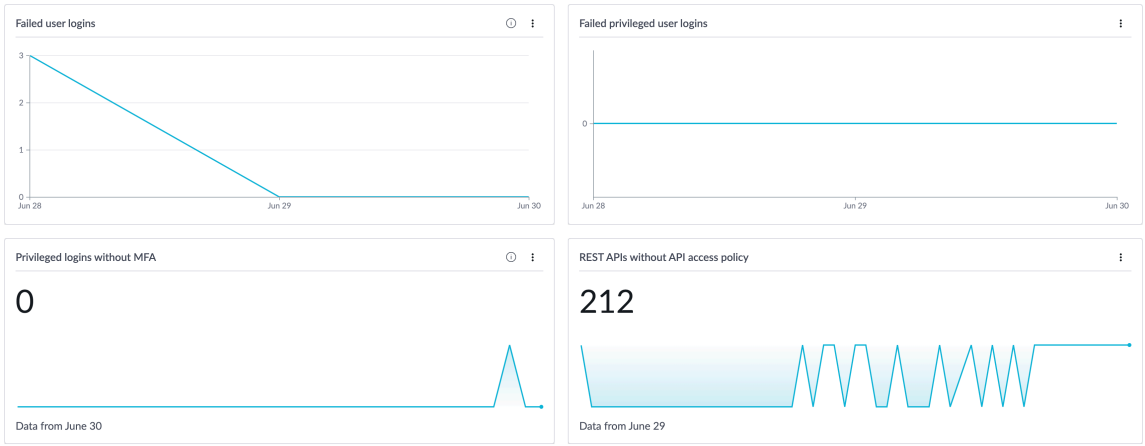
Active users

Displays a count of active users on your Users [sys_user] table. Active users are user records where the **Active** field is selected. Select this widget to see details on these records in the Active Sessions section of Security metrics.

Active integration accounts

Displays a count of integration accounts on your Users [sys_user] table. Integration accounts are user records where the **Web service access only** field is selected. Select this widget to see details on these records in the Active Sessions section of Security metrics.

Active privileged accounts



Displays a count of active privileged users on your Users [sys_user] table. Privileged users are user records where the **Active** field is true, the **Internal Integration User** is false, and **Internal Integration User** is inactive. Select this widget to see details on these records in the Active Sessions section of Security metrics.

Never logged-in users

Displays a count of users on your Users [sys_user] table created in the last 60 days, and have no value in the **Last login time** field. Select this widget to see details on these records in the Active Sessions section of Security metrics.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Login protection

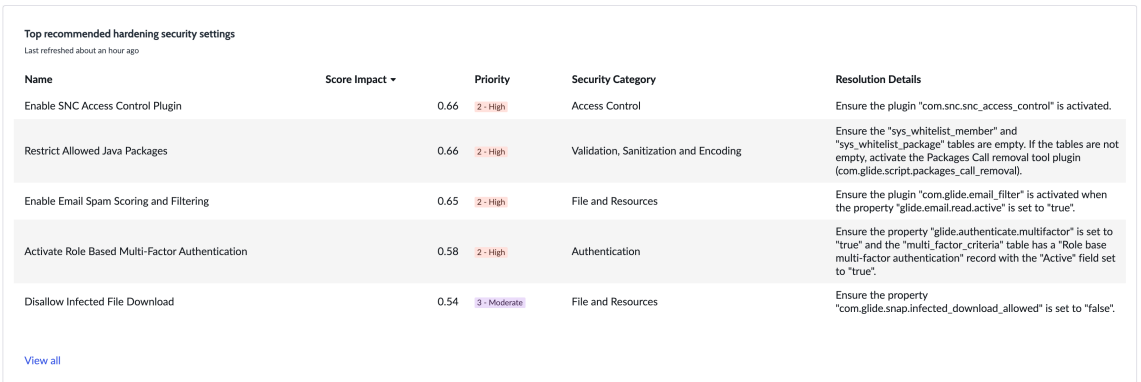
The **Login protection** section includes information on failed logins, including failed login attempts for privileged users. These widgets include a line graph showing changes to this information over time. Select a widget to view more detail.

Failed user logins

Displays a count of failed user login attempts. Select this widget to navigate to see details on failed logins in Security metrics.

Failed privileged user logins

Displays a count of failed user login attempts from privileged accounts. Privileged users are user records where the **Active** field is true, the **Internal Integration User** is false, and **Internal Integration User** is inactive. Select this widget to navigate to see details on failed logins in Security metrics.

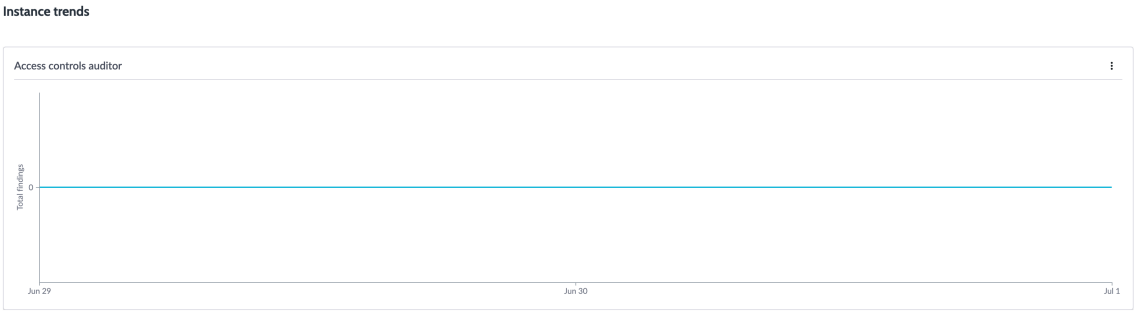


Privileged logins without MFA

Displays a count of privileged accounts that aren't configured for multi-factor authentication (MFA). Select this widget to navigate to see a list these accounts in Security metrics.

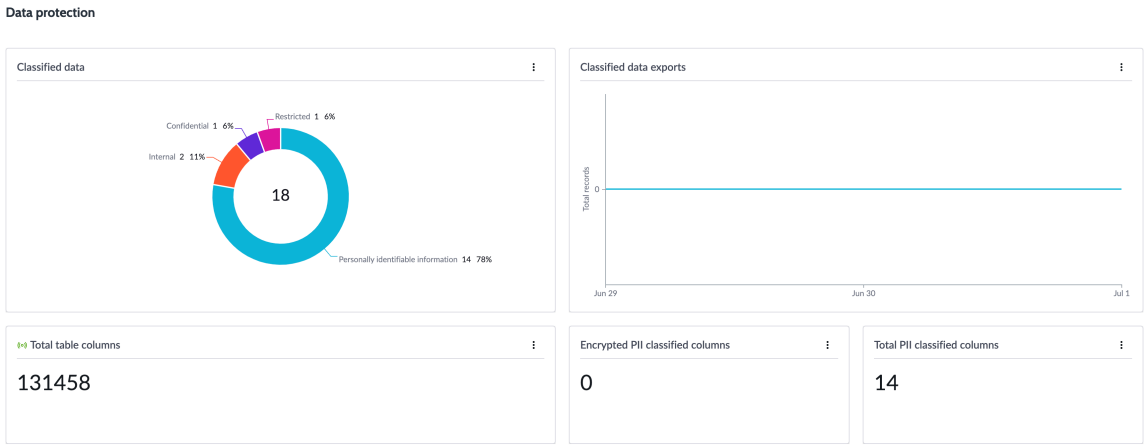
REST APIs without API access policy

Displays a list of REST APIs that aren't restricted with an API access policy. Select this widget to navigate to see a list these REST APIs in Security metrics.



Instance hardening

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



The **Instance hardening** section contains recommended hardening security settings that you can change to improve instance security. Use this section to see the priority and potential impact of these changes.

Instance trends

The **Instance trends** dashboard displays the results of the access controls auditor scan suite.

Data protection

Use the **Data protection** section to see an overview of classified data, such as personally identifiable information (PII). The dashboard also tracks exports of classified data.

Classified data

Displays a pie chart of classified data on your instance, separated by type. Select a section of the chart to view details on these records. For details on data classification, see Data classification.

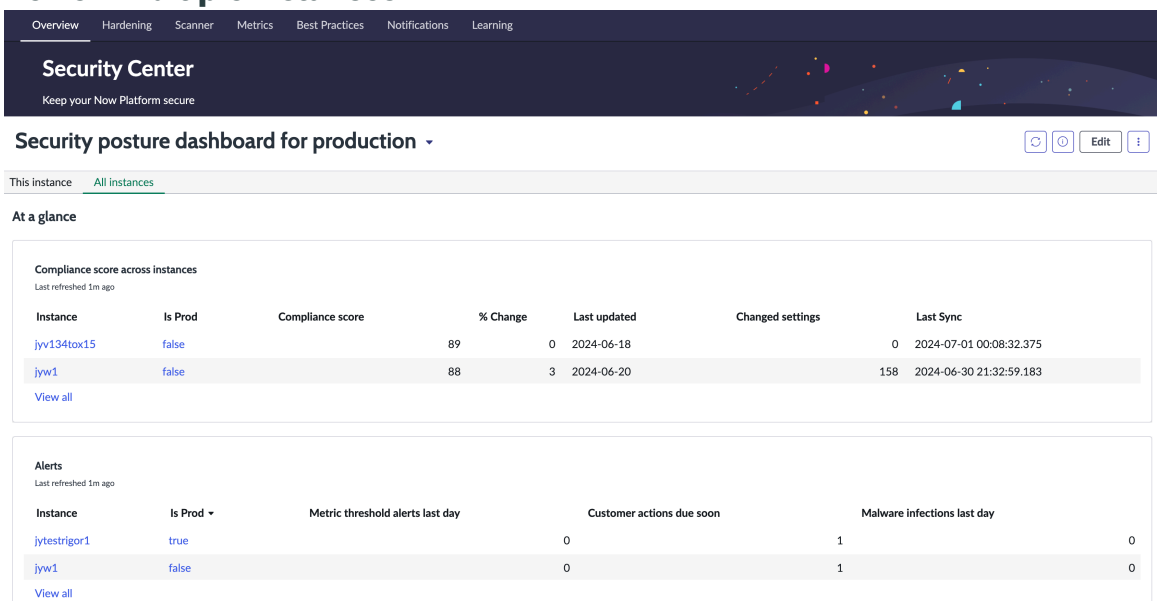
Classified data exports

Displays a count of classified records that have been exported from your instance. Select this widget to see a list of classified exports in the Export section of Security metrics.

Total table columns

Displays a count of all columns(fields) in tables on your instance. Select this widget to review these columns in the Data Classification section of Security metrics.

Encrypted PII classified columns



Displays a count of encrypted records classified as Personally Identifiable Information (PII). Select this widget to review these records in the Data Classification section of Security metrics.

Total PII classified columns

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Displays a count of all records classified as Personally Identifiable Information (PII). Select this widget to review these records in the Data Classification section of Security metrics.

Review multiple instances

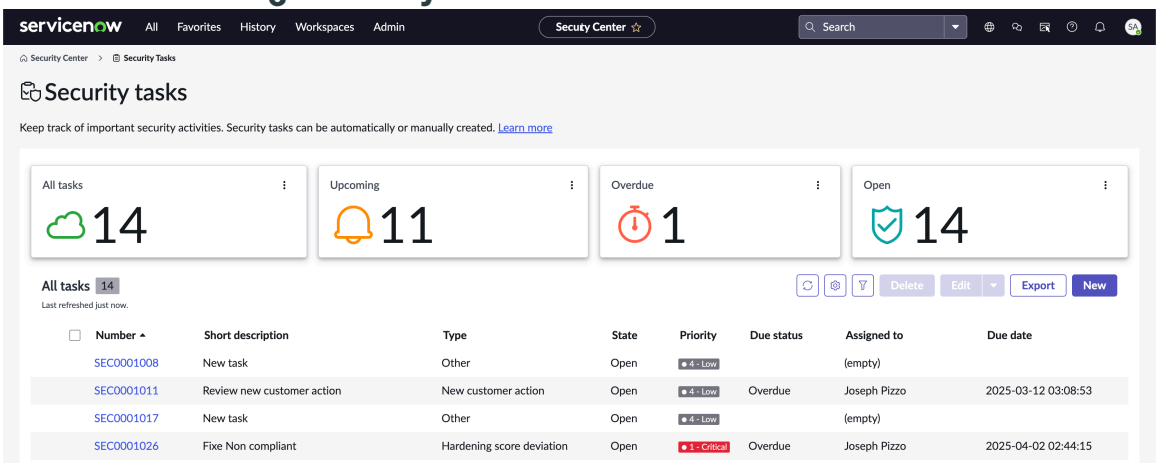
View the security posture of your non-production instances without leaving your production instance using the **All instances** tab at the top of the dashboard. The **All instances** tab displays a condensed version of the same information as the **This instance** tab, but also includes data from all your non-production instances.

By default, the **All instances** tab displays information on the production instance you're logged in to, and all non-production instances across all your production environments.

You may add or remove instances that appear on this dashboard by modifying your trust configuration. Providing data visibility between instances allows them to appear within your dashboard. For details on this process, see Basic trust configuration for data sync applications.

Dashboard customization

The instance security posture dashboard can't be customized, but you can duplicate the dashboard by selecting the **More Actions** (⋮) icon and selecting **Duplicate**. You can change the duplicate dashboard.



Security Tasks

Use Security Tasks to monitor, prioritize, and assign all your security-related tasks in one place.

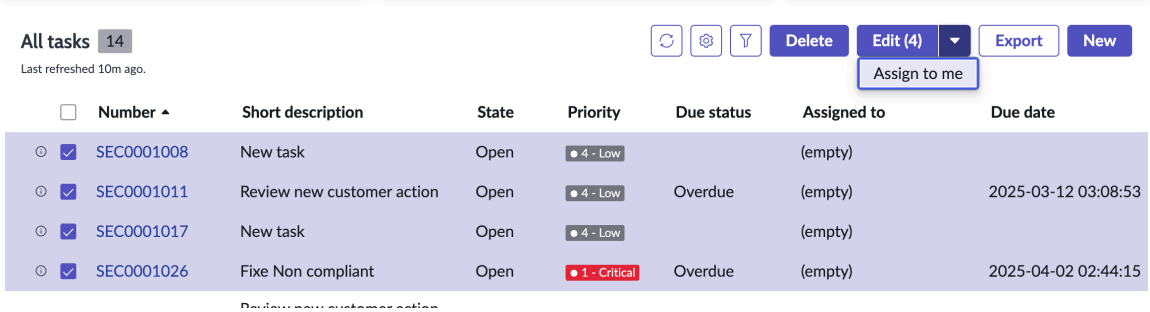
Save time tracking and organizing all the tasks needed to improve and maintain your instance security posture using Security Tasks.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Review and manage Security Tasks

Access the Security Tasks by navigating to **All** > **Security Center** > **Security Tasks**. By default, all tasks are displayed in the list. You can easily filter upcoming, overdue, or open tasks by selecting the cards above the list. These cards also display the current count of tasks in each of these categories. You can further refine your filter by using the normal table field filtering options and then selecting the filter button ( ), then selecting the Advanced view button to create and save a custom filters to use later.

User roles

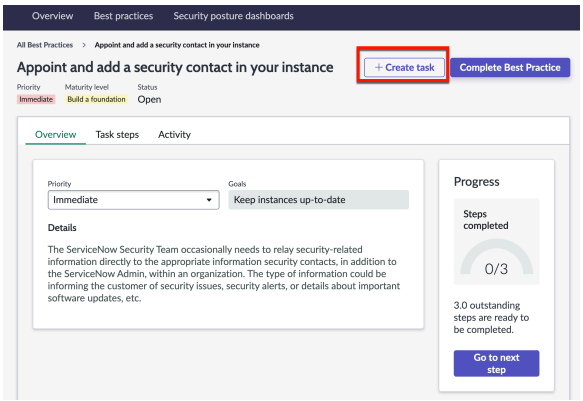


The Security Tasks use the following roles:

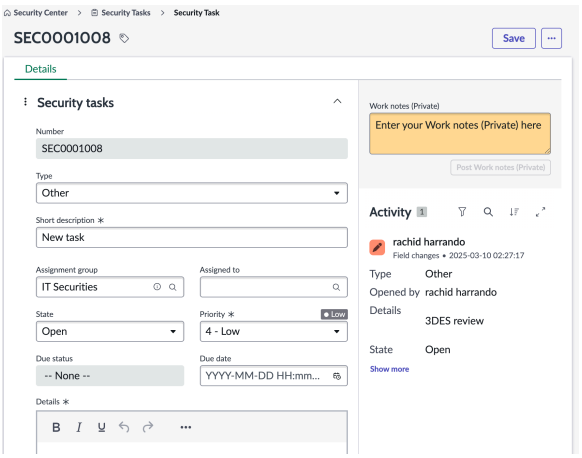
User	Required role	Description
System Administrator	admin	System Administrators can view, create, assign, and delete Security Tasks.
Security Center Viewer	sn_vsc_security_center_viewer	Viewers can view, but not create, delete or edit Security Tasks.
Security Task Manager	sn_vsc_task_manager	Security Task Managers can work on assigned tasks, view task manager-related pages, and create and manage tasks within Security center. They can view tasks assigned to other users but can't edit tasks assigned to other users. Task managers can't access non-task manager pages in Security Center.
ITIL	itil	ITIL users can interact with Security Tasks assigned to them, but can't view all tasks as the admin and Security Task manager roles can.

Quickly assign to yourself Security Tasks

Use the check boxes to the left of the items in the list to select multiple items. When one of more tasks is selected, you can use the **Delete** button to delete the selected tasks, or the **Edit** button to assign the selected tasks to yourself.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Create Security Tasks

Create a Security Task with the **+Create Task** button, which is available various platform security pages.

For example, in Security Center, on the Best Practices tool details page, the admin can select the **+Create Task** button to create and assign a task to complete this best practice.

Automatically generated tasks

Security Tasks can be automatically generated. Automatic Security Task generation is triggered by an associated event that occurred on the platform. Learn more about generated Security Tasks in Automatic Security Task generation.

Edit and assign Security Tasks

Edit Security Tasks to assign them to users, define due dates, and provide additional details to the users who will complete these tasks. For details, see Edit Security Tasks.

Export tasks

You can export Security Tasks into the format of your choice. For details, see Export Security Tasks.

Automatic Security Task generation

Learn about how and when your instance generates Security Tasks.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Automatically generated Security Tasks

Security Tasks can be automatically generated. Automatic Security Task generation is triggered by an associated event that occurred on the platform. For example:

Metrics threshold breached

A Security Task is generated for a metric when it's threshold is breached. There's only one open task for a metric, even if the same metric has multiple breaches. If a Security Task for a breached metric is closed, a new task is generated is the threshold is breached again.

Event notification

A Security Task is generated when a security event notification triggers (meets conditions of it's policy). As with metrics, there's only one open task for a policy, with a new task being generated if the previous one is closed, and the notification triggers again. For details on security event notifications, see Security Event Notifications.

Hardening score deviation

When the hardening score degrades below the configured threshold value (default 3), a Security Task is generated. For example, if the hardening score is 97, and is 94 the next day, a Security Task is created just after the score of 94 is calculated. Only a single open task is created. The platform will not generate another task if the score lowers again the next day from 94 to 91. For details on your hardening score, see Hardening compliance score trend.

Customer Action

A Security Task is generated whenever a Customer Action is installed. For details on Customer Actions, see Customer Actions.

Banner announcement

A Security Task is generated for each new banner announcement. For details on banner announcements, see Security banner announcements.

Automatically generated security settings

Configuration options for automatically generated Security Tasks are found in the security center properties page. Find these settings by navigating to **All** > **Security Center** > **Security Center Properties**.

Enable/Disable automated Security Tasks

When the **Yes/No** field is selected, automated Security Tasks are enabled on your instance.

Hardening score degradation threshold

The value in the field represents the amount by which the hardening score must degrade (since the last daily score) to generate a Security Task. This value must be a positive integer. The default value is 3.

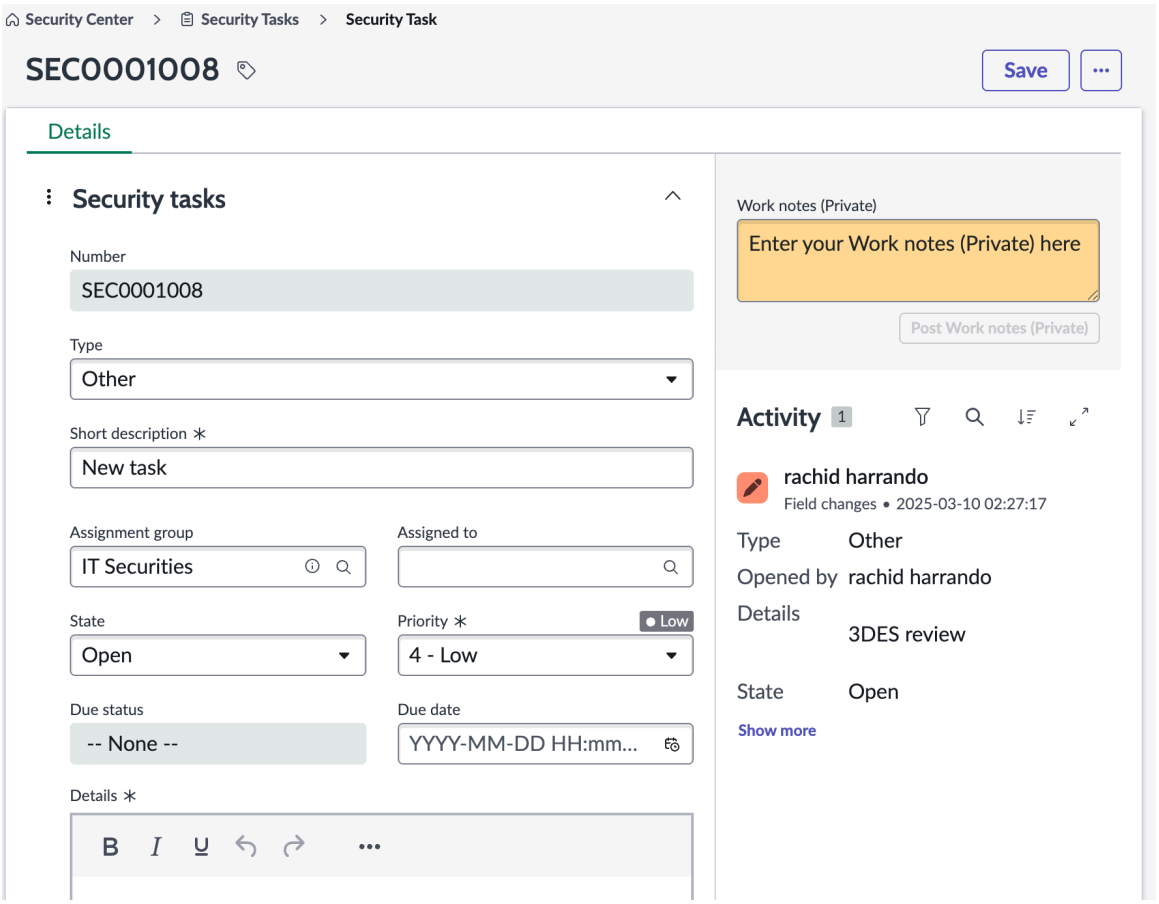
Edit Security Tasks

Learn how to create, edit, delete, or export Security Tasks in Security Center

Before you begin

Role required: admin or sn_vsc_task_manager

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

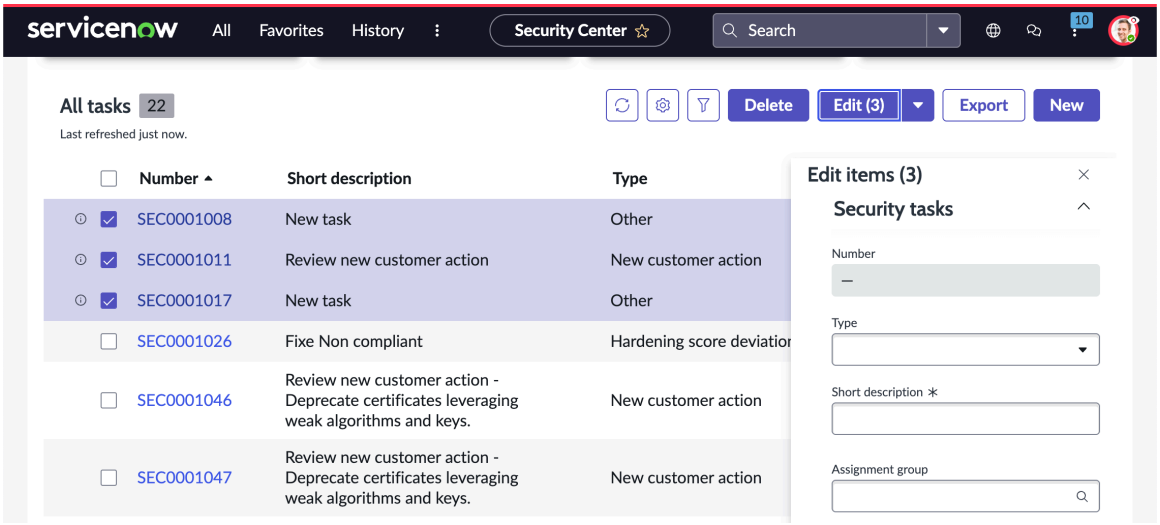


Procedure

1. Access your Security Task list by navigating to **All** > **Security Center** > **Security Tasks**.
2. From the Security Task list, you can edit your Security Tasks in two ways:

Edit in the Security Task form

Select a Security Task number from the list to open the Security Task record and see its details. Here you can edit, assign to another user, and add work notes.



Important: Remember that users who are assigned tasks must be admins or have the sn_vsc_task_manager role.

Edit from the Security Task list

Select one or more Security Tasks by selecting on its check box on the left and then select the **Edit** button.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. Fill in the fields as needed:

Field	Description
Number	Automatically generated number used to identity the task
Type	Select a task type: ○ Metrics threshold breached ○ New Customer Action ○ Event notification ○ Hardening score deviation ○ New banner announcement
Short description	Brief description of the task
Assignment group	Assignment group for the task
Assigned to	Person assigned to the task. This user must be in the assignment group selected in the **Assignment Group** field, and have the *admin* or *sn_vsc_task_manager* role.
State	State of the task: ○ Pending ○ Open ○ In Progress ○ Closed ○ Canceled
Priority	Priority of the task: ○ 1- Critical ○ 2- High ○ 3- Moderate ○ 4- Low

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Due status	Whether the task is **Upcoming** or **Overdue**, depending on the date in the **Due date** field.
Due date	The date and time by which the task needs to be completed.
Details	Used to provide details, links, or other information users need to know about this task.
Work notes	Notes about this task. Notes entered into this field are timestamped and displayed on the Activity list on the right of the screen.
Work notes (private)	Work notes can be privately added by entering them into this field and selecting the **Post work notes (private)** button.

4. Select **Save** to save the Security Task record, if you are editing a record from the list, select **Update**.
5. **Optional:** If needed, you can delete a task from the list by selecting on its check box on the right, and selecting **Delete**, or in the form by selecting the more icon (...), then selecting **Delete**.

Export Security Tasks

Learn how to export Security Tasks into files you can download and use in other software.

Before you begin
Role required: admin

Procedure

1. Access your Security Task list by navigating to **All** > **Security Center** > **Security Tasks**.
2. Select one or more Security Tasks by selecting on its check box on the left
3. Select the **Export** button.
4. Under **File type**, select the file format you want the Security Tasks exported to. You can select from Excel, CSV, JSON, or PDF formats.
5. Under **Delivery Type**, select either **Download** or **Email**.

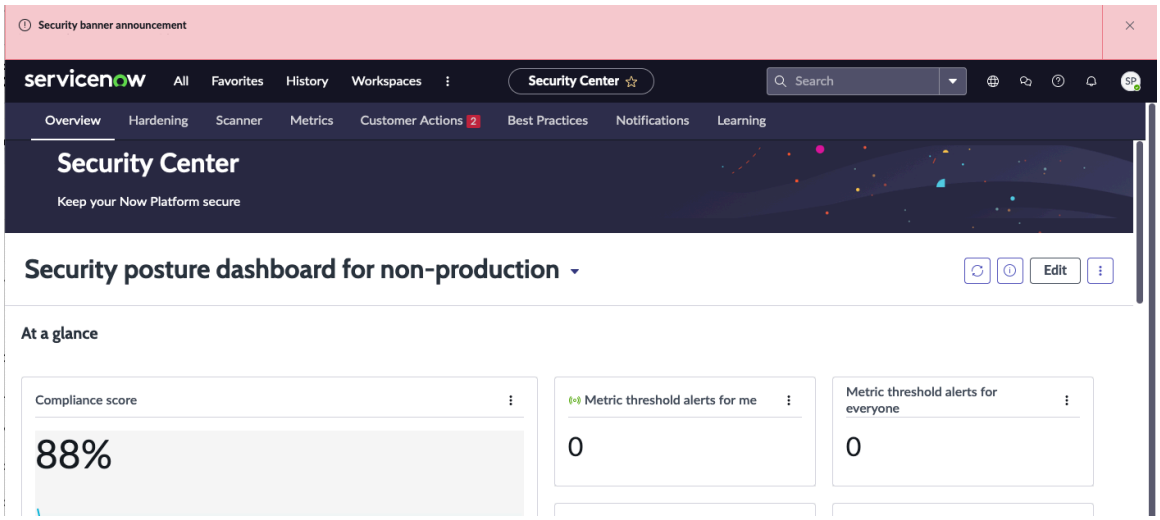
   Download

   The export file is downloaded using your browser.

   Email

   The **Email** field displays. Enter a email address in the **Email** field, and the export file is delivered to the specified email address.

Security learning



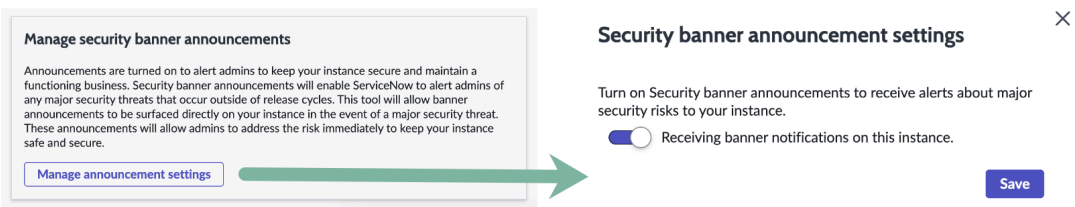
Access security learning materials from a single page.

Read security white papers, ebooks, knowledge base (KB) articles, product documentation, and community discussions from a consolidated view by navigating to **Learning**. The content is organized by headings and descriptive UI cards to make it quick for you to pinpoint the correct resource.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Security banner announcements

Enable security banner announcements to stay informed about urgent and critical security alerts using high visibility banners visible to administrators within the instance UI.



Security banner announcements are announcements displayed to customer administrators, sent by ServiceNow, to keep you informed about fixes for potential security threats that were discovered recently. These alerts contain a summary of the security risk and include a link where you can learn more and act to secure your instance.

Administrators can dismiss banner by selecting the close (x) button, but the banner re-appears with each new session until the banner expiration date is passed. Administrators can disable banner announcements by setting the *`sn_vsc.configure_customer_push_action`* system property value to `false`. The duration for which the banner appears is controlled by **Start** and **End** field values for the banner. These fields are found in banner's record in the Banner Announcement [sys_ux_banner_announcement] table.

Enable or disable security banner announcements

The security banner feature is enabled by default. To enable or disable security banner announcements, navigate to **System Security** > **Security Center** > **Notifications**. From this page, select the **Manage announcement settings** button.

Granular roles for Security Center

Use the new Security Center admin role to grant users security center administrative capability without using the admin role.

Beginning with the Security Center 3.2 update available in the ServiceNow Store, the Security Center Admin (sn_vsc.security_center_admin) role is available. This role allows users to manage

Security Center configurations and access controls while enhancing security through least-privileged access.

Granular Role	Description
sn_vsc.security_center_admin	Provides admin level access to Security Center consoles and tools. Users with this role can also create and manage security tasks. This role contains the following roles: • mi_admin • access_analyzer_admin • pa_admin • scan_user data_classification_auditor • sn_ace.ace_user • antivirus_viewer • sn_vsc.task_manager • sn_mif.mif_read • sn_cicd.sys_ci_automation

Hardening settings

The ServiceNow Security Center (SSC) hardening settings content contains detailed descriptions and compliance values for the security-related system properties and plugins in the ServiceNow AI Platform. You can set these properties using the hardening settings app in the Security Center.

Overview and purpose

The Security Center calculates a daily compliance score, expressed as a percentage that is based on how compliant your current instance security settings are with the compliance values in Security Center hardening settings.

You can manage the specific security configuration settings that may affect the score for your instance directly from the Security Center.

The hardening settings configurations are explained with several attributes described in the table.

Hardening settings configuration details

Configuration attribute	Description
Overview	Provides a high level overview of the recommendation.
Configuration name	The property or plugin name.
Configuration type	Describes where the property can be configured outside of the Security Center, such as in system properties (*sys_properties_list.do*).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Hardening settings configuration details (continued)

Configuration attribute	Description
Data type	Describes the type of value required for the configuration. Examples are true/false boolean, installation, plugin, string, etc.
Recommended value	The value that is recommended by the Security Center to enhance security compliance in your instance.
Default value	The value that the configuration is set to in the base system.
Category	The name and link to the category for the hardening setting.
Security risk	**Severity score**: The score indicates the potential security risk to your instance as per the likelihood of the vulnerability to be exploited. The security vulnerability is considered and scored individually using the CVSS (Common Vulnerability Scoring System) score on a scale ranging from **0.0** to **10.0**. See https://nvd.nist.gov/vuln-metrics/cvss/v3-calculator for additional information.
	Severity rating per CVSS score: • Critical: 9.0-10.0 • High: 7.0-8.9 • Medium: 4.0-6.9 • Low: .01-3.9 • None: 0.0
	Security risk details: Describes the importance of the setting configuration and the risk of not utilizing the recommended configuration.
Dependencies and prerequisites	Related settings or configurations that are required before or in conjunction with the hardening configuration.
Functional impact	The impact this hardening setting has on the operation of your instance.
References	Links to configuration documentation or other helpful information.

Note: Some of the configurations can only be completed by Customer Service and Support and will be indicated as such.

To learn more about ensuring your instances meet hardening requirements, see Security hardening.

Other resources

For user reference, the ServiceNow AI Platform maintains extensive configuration capabilities information in the product documentation. You access most of the security content using the links found in Secure your instance. Also, see the following:

Hardening settings baseline versions

Explore how baseline versions for hardening settings align with family and store releases.

Security Center works by ingesting a subset of system properties from an instance and displaying its configuration details, along with the security impact of non-compliance within the app. The baseline serves as the reference point for the system properties that are ingested with each release of the Security Center app.

Hardening settings baseline overview

Security Center version	Hardening settings baseline version	Supported families	Store release date	Installed by default with
SSC v 3.5	Baseline v9.0	Brazil	September 2026	Brazil
SSC v 3.3	Baseline v8.0	Australia	March 2026	Australia
SSC v 3.2	Baseline v7.0	Zurich	August 2025	Zurich
SSC v 2.2	Baseline v6.0	Xanadu, Yokohama	May 2025	Store Only
SSC v 2.0	Baseline v5.0	Xanadu, Yokohama	November 2024	Yokohama
SSC v1.6	Baseline v4.0	Washington DC, Xanadu	August 2024	Store only
SSC v1.5	Baseline v4.0	Washington DC, Xanadu	May 2024	Xanadu
SSC v1.3	Baseline v2.0	Vancouver, Washington DC	Nov 2023	Washington family
SSC v1.2	Baseline v1.0	Utah, Vancouver	Aug 2023	Store only
SSC v1.1	Baseline v1.0	Utah, Vancouver	May 2023	Vancouver family

New hardening settings

New hardening settings are broken out by baseline release.

New hardening settings for baseline 9.0

New hardening settings are available in Security Center baseline version 9.0.

- Apply static analysis to all users
- Capture audit records for Code Signing-protected records
- CSRF enforcement for session-authenticated REST APIs
- Disable log-and-allow mode for cross-scope dot-walk access
- Enable anti-CSRF token
- Enable CRL-based certificate revocation checking for outbound HTTP requests

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Enable CSRF enforcement for authenticated processors
- Enable MID Server governance checks
- Enable sanitization of inbound virtual agent chat messages
- Enable static analysis
- Enable synchronous mode for static analysis
- Enforce CRL certificate revocation checking for outbound HTTP requests
- Enforce cross-scope table access when performing dot-walk
- Enforce domain access control on all tables
- Enforce least privilege on scoped MCP OAuth tokens
- Enforce signature verification for Flow Designer artifacts
- Enable KittyScript sandbox security enforcement
- Enforce KittyScript validation for guest sessions
- Enforce strict deny for ACLs referencing only deleted or non-existent roles
- Ensure MID Server Users Have Appropriate Access Levels
- Limit basic authentication restriction allowed users
- Limit basic authentication restriction allowed roles
- Minimize session activity timeout duration
- Normalise REST API access policy key generation
- Prevent disabling of data separation enforcement
- Prevent unauthenticated roleless ACL in scripted ACLs
- Restrict exposure of validation error details to end users
- Restrict MID IPKI registration key retry attempts
- Restrict platform analytics export to authorized roles
- Restrict script authorship to authorized users only
- Require JWT trust verification for guest embedded sessions
- Restrict vault code signing audit exclusion to defaults
- Set basic authentication restriction default decision

New hardening settings for baseline 8.0

New hardening settings have been released with Security Center baseline version 8.0.

- Enforce field-level ACLs on records created from the filtered list view UI query string
- Enable IAM and boundary checks for Amazon Bedrock access
- Enable Guardian for External Agents
- Enable Identity and Access Audit tool
- Validate MIME Type of Attachments from Inbound Emails
- Enable Jelly JS interpolation protection
- Prohibit Use of KBA as Single Factor for AI Voice
- Require Multi-Factor Authentication for AI Voice Agent
- Log Impersonation History

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Validate MIME type for multi-extension filenames and polyglot files
- Enable Jelly JS interpolation protection for nested expressions
- Enable Role Masking for Agents
- Disable adding default roles to skill ACLs
- Prevent Reuse of REST API Sessions in UI/Web
- Enable Anti-CSRF Token for Userperf
- Track Impersonation Events
- Disable Voice Chat Guest Impersonation
- Prevent OAuth Clients from Using Implicit Grant
- Enforce Scope Access Controls on New Tables

New hardening settings for baseline 7.0

New hardening settings have been released with Security Center baseline version 7.0.

- Enable Cross Scope Privilege Checks on Service Portal Form [New in Security Center 7.0]
- Validate query ACLs on Glide DB functions [New in Security Center 7.0]
- Use Document Classification to limit publicly accessible documents [New in Security Center 7.0]
- Restrict write access on system fields to admin users [New in Security Center 7.0]
- Require approval for agent-based Office 365 group membership changes [New in Security Center 7.0]
- Exclude Sensitive Tables and Fields from Data Generation [New in Security Center 7.0]
- Enforce Read Roles for Catalog Variable Search [New in Security Center 7.0]
- Enforce valid query string choice [New in Security Center 7.0]
- Restricted Binding functionality in Case Bearer authorization
- Disable resource owner password credentials (ROPC) in OAuth 2 token grants [New in Security Center 7.0]
- Enforce certificate trust [Updated in Security Center 1.3, removed in 2.0, added in 7.0]
- Prevent usage of 3DES keys
- Allow HTML Links to Trusted Domains in the Description Fields of the Impact Workspace Module [New in Security Center 7.0]
- Ensure Contextual Search Do Not Contain An Unvalidated Redirect [New in Security Center 7.0]
- Sanitize HTML in the Description Fields of the Impact Workspace Module [New in Security Center 7.0]

New hardening settings for baseline version 6.0

New hardening settings have been released with Security Center baseline version 6.0.

- Enforce application specific ACLs only for application data
- Disable legacy JQuery UI usage
- Display recommendations for high risk UI pages
- Enforce current password policy compliance requirements on login

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Prevent Users From Accepting Warning To Bypass CSRF Validation [Updated in Security Center 1.3 and 1.5]
- Require Minimum and Maximum Password Length
- Limit session length for high assurance sessions
- Disable deprecated TLS versions
- Disable local login for users with Single Sign-On (SSO) enabled
- Reduce allowed bypasses for multifactor setup
- Prevent impersonating user from viewing application data
- Prevent verbose HTTP request logging
- Enable relay state in SAML requests to prevent replay attacks
- Minimize failed login attempts for high assurance sessions
- Apply continuous authentication policies to mobile sessions
- Disable use of TripleDES/3DES encryption algorithm

New hardening settings for baseline version 5.0

New hardening settings have been released with Security Center baseline version 5.0.

- Enforce ACL on HR lifecycle events data
- Sanitize All Translated HTML Fields
- Configure service portal widgets allow list
- Enforce ACL on HR Core Data [New in Security Center 2.0]
- Enforce ACL on HR Virtual Agent Data [New in Security Center 2.0]
- Configure service portal widgets table allow list
- Enforce Security Scope for Service Application Information [New in Security Center 2.0]
- Prevent empty ACL creation
- Prevent Unauthenticated Access to Virtual Agent Embedded Web Client
- Set automatic token cleanup for token credentials
- Restrict Global App Development by Role
- Enable ACLs for Encoded Query in Simple List Widget
- Invalidate Session After OAuth Token Expiration [New in Security Center 2.0]
-
- Restrict Impersonation to Admin

New hardening settings for baseline version 4.0

New hardening settings have been released with Security Center baseline version 4.0.

- Review extraneous explicit role access control conditions [Removed in Security Center 1.5]
- Enable work order management query rules for service organizations
- Restrict flow context read access
- Limit the policy-based mobile refresh token interval
- Enable policy based session access for mobile
- Prevent inactive users from logging in

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Configure event management assignment group admin roles [New in Security Center 1.5]
- Enforce Security Scope for Agent Workspace for HR Case Management [New in Security Center 1.5 and updated in 2.0]
- Enforce security scope license and permit playbook [New in Security Center 1.5 and updated in 2.0]

New hardening settings for baseline version 2.0

New hardening settings have been released with Security Center baseline version 2.0.

- Ensure archive table ACLs are checked
- Enforce application scope restrictions [New in Security Center 1.3 and removed in 1.5]
- Enable the hardened java security manager
- Verify certificate revocation
- Clear pasteboard when app backgrounds
- Enable protected tables plugin
- Enforce strict elevate privilege
- Limit integrations' active session life span
- Proactively invalidate sessions after defined durations
- Enable MID audit log
- Use of secure insert multiple operation within import set API
- Enforce OCSP check on network error
- Enforce security rules to sharing dashboards
- Restrict oauth parameters to POST body
- Limit attachment size in training and prediction flows for GraphQL endpoints [New in Security Center 1.3 and updated in 1.5]
- Disable GlideRecord scope fencing legacy behavior
- Required JMS connection factories
- Limit attachment size in training and prediction flows [New in Security Center 1.3 and updated in 1.5]
- Log session audit events
- Require write access to access service catalog add item page
- Define active session timeout exception roles
-
- Enforce scoped ACL access for information request playbooks [New in Security Center 1.3 and updated in 1.5]
-
- Ensure dashboards creation/deletion requires access check [New in Security Center 1.3 and updated in 2.0]
- Enforce device encryption and passcode requirements [New in Security Center 1.3]
- Validate file MIME type in AttachmentCreator web service
- Verify certificate revocation
- Check impersonation on ACL evaluation in HR App [New in Security Center 1.3 and updated in 1.5]

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Require CAPTCHA for guest walk-up experience in customer service application
- Require Authentication on Event Management HTTP Processor [New in Security Center 1.3, Updated in 1.5, and removed in 2.0]
- Limit guest's active session life span
- Disallow target cloning [New in Security Center 1.3]
- Set safe content security policy for SVG files
- Anti-CSRF token validation time
- Restrict knowledge bases access
- Enforce scope security for public sector digital services [New in Security Center 1.3]
- Restrict HR case updates from personal emails
- Limit UI active session life span
- Enforce secure referrer policy

Updated hardening settings

Updated hardening settings are broken out for each baseline release.

Updated hardening settings for baseline version 9.0

Some hardening settings have been updated with the release of Security Center baseline version 9.0.

Documentation	Updates
Disable AJAXEvaluate	Default value • (Old) <blank> • (New) false
Enforce field-level ACLs on records created from the filtered list view UI query string	• Short description ○ (Old) Enforce field-level ACLs on records created from the query string of the Filtered List view UI of a table ○ (New) Enforce field ACLs on records created from Filtered List view UI query string • Functional impact ○ Old When com.glide.acl_check_all_filter_on_new is set to true, then ACLs may prevent fields included in the filter query string from affecting the value of fields in a created

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	record when the creation is triggered from the list view UI of a table. However, this previous behavior was incorrect as it bypassed ACLs and allowed user without creation access to a field to modify its value. ○ New When the com.glide.acl_check_all_filter_on_new is set to true, ACLs are enforced for fields included in the filter query string during record creation from the list view UI. This prevents users without create access from modifying protected fields through filter parameters.
Escape XML markup	Default value • (Old) <blank> • (New) true
Turn off verbose SQL error messages for import processor	Default value • (Old) <blank> • (New) true
Require authorization for excel requests	Default value • (Old) <blank> • (New) true
Enable protected tables plugin	• Remediation ○ (Old) Set the Glide Property com.glide.security.protected_table.enabled to true. This requires a user with the security_admin role. ○ (New) Enable table protection through the guided activation flow:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	1. Navigate to the Protected Tables plugin's guided activation flow. 2. Complete the activation process to enable table protection. Only users with the security_admin role can activate this control. Important: Don't enable this control by directly editing the property com.glide.security.protected_table.enabled outside that guided activation flow. Default protected tables: syslog, syslog_transaction, sys_outbound_http_log, sysevent, sys_audit, sys_push_notification, protected_table_configuration, syslog_app_scope To extend protection to additional tables, configure insert, update, and delete protection rules for each additional table and operation in the Protected Table Configuration list. • Security risk ○ Old Log integrity must be maintained to allow discovery of malicious activity. ○ New When disabled (the default), Protected Tables protections don't apply, allowing maintenance-role users to modify or delete critical audit and security logs without detection. An attacker with maintenance credentials could tamper with syslog, sys_audit, and sysevent entries to cover malicious activity and evade forensic investigation. Disabling this property compromises the audit trail needed to detect and investigate security incidents. • Functional impact ○ Old <blank> ○ New Enabling the com.glide.security.protected_table.enabled property causes create, update, and delete attempts on tables in the Protected

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	Table Configuration list to be evaluated. Depending on that table's configured protection level, the attempt is blocked, logged, or ignored. The level shipped per table is not fixed. It depends on how long the Protected Tables plugin has been installed, so confirm the actual values on your instance rather than assuming a table is blocking. One exception holds everywhere: insert attempts on sysevent are never blocked or logged, since normal processing inserts sysevent records continuously. A refused attempt shows the message "Modifications to <table> have been refused due to the Protected Table configuration. Please contact your system administrator." Any integration or business rule currently writing to or deleting from a blocking table will start failing once this property is enabled. • Default value ○ Old <blank> ○ New false
Enable Jelly JS interpolation protection	• Functional impact ○ Old <blank> ○ New Enabling this property causes the platform to reject Jelly JavaScript expressions that aren't explicitly recognized as safe or marked as SAFE. Instance owners should test custom UI pages, macros, and portal widgets that use Jelly-interpolated JavaScript expressions after making this change, and confirm that legitimate expressions continue to render as expected. Custom Jelly content that relies on dynamic, unmarked expressions may need to be updated to use the SAFE designation to continue functioning. • Default value ○ Old <blank> ○ New true in Australia and newer, false prior • Fallback value

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	long even without activity. This could provide too large of a time window to enable session hijacking attacks. ○ (New) The glide.ui.session_timeout property controls the inactive session timeout for authenticated users, specified in minutes. If this property is not set to the recommended value of 30 minutes or less, the session may remain valid for extended periods without user activity. A long session timeout allows inactive sessions to remain valid for extended periods, increasing the chance that an attacker could hijack the session before it expires. • Remediation ○ (Old) Ensure the property glide.ui.session_timeout is set to 60 or less. ○ (New) 1. Navigate to /sys_properties_list.do on the instance. 2. Ensure the glide.ui.session_timeout property does not exist in the sys_properties table or is set to 30 minutes or less. • Functional impact ○ (Old) <blank> ○ (New) Reducing the glide.ui.session_timeout property lowers the amount of idle time allowed before a user's session ends automatically, requiring re-authentication. Users who leave a session idle longer than the configured value (for example, while completing a long form, waiting on an approval, or stepping away between tasks) will be logged out and must sign in again. Administrators should verify that long-running interactive workflows still complete comfortably within the new timeout window. Confirm that any

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
Implement the x-frame-options: SAMEORIGIN security header	Default value • (Old) <blank> • (New) true
Maximize reset password SMS complexity	Default value • (Old) <blank> • (New) 6
Limit integrations' active session life span	• Description ○ (Old) This configuration will enforce max lifespan on active guest HTTP sessions irrespective of inactive timeout. The configured value is in minutes and the value of zero will disable timing out the active sessions. A larger maximum lifespan could allow an attacker to persist in a stolen session for longer, increasing the scope of a security incident. This particular property is limited to integrations that have low-privilege access to an instance. ○ (New) The *glide.integrations.active.session.life_s* property enforces the maximum lifespan on active integration HTTP sessions, regardless of session inactivity. The configured value is in minutes. A value of zero disables the lifespan limit entirely, allowing sessions to persist indefinitely until the inactive timeout fires. This particular property is limited to integrations that have low-privilege access to an instance. A larger maximum lifespan allows an attacker to persist a stolen session for longer, increasing the scope of a security incident. • Remediation

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	○ (Old) Set the Glide Property 'glide.integrations.active.session.life_span' to a value greater than 0 and less than or equal to 720. ○ (New) 1. Navigate to /sys_properties_list.do on the instance. 2. Ensure the *glide.integrations.active.session.life_s* property exists and is set to a value greater than 0 and less than or equal to 720 minutes. • Functional impact ○ (Old) <blank> ○ (New) Integration sessions that exceed the configured lifespan are silently invalidated and reissued a new session ID. The integration user sees no error, but any session-scoped state accumulated during that session is lost and starts fresh. • Dependencies and prerequisites ○ (Old) <blank> ○ (New) This control interacts with the *glide.integration.session_timeout* property, which controls the integration idle-session timeout duration. The platform requires the active session maximum lifespan to be greater than or equal to the integration idle timeout. If the active session lifespan is configured to a value lower than the idle-session timeout, the platform automatically increases the effective lifespan to match the idle-session timeout and logs a warning message.
Limit concurrent sessions across all nodes	Default value • (Old) <blank> • (New) true

Documentation	Updates
Enable account recovery	• Description ○ (Old) This property controls the account recovery feature, which binds the ability to bypass single sign-on to specifically designated administrators. If "glide.sso.acr.enabled" is not set to the recommended value of "true", then the local interactive log-ins (username or password based) will be remain enabled when single sign-on is enabled on the instance. ○ (New) The glide.sso.acr.enabled property controls whether the Account Recovery (ACR) feature is available on an instance configured for Single Sign-On (SSO) authentication. When set to the recommended value of "true", the platform blocks turning on multi-SSO until account recovery is enabled. At least one user account must be enrolled for it. It also confines any session authenticated through the recovery path to writing only SSO- and account-recovery-related configuration. This preserves a controlled, auditable path back into the system for users who lose access to their normal SSO credentials. • Security risk ○ (Old) Eliminating local interactive log-ins reduces the potential for unauthorized access to the instance. ○ (New) Without an account recovery path, a user who loses access to their normal sign-in method has no supported way back into the system. That gap commonly pushes administrators and help desks toward manual, ad hoc identity verification workarounds to restore access. Those workarounds are a well-known target for social engineering and account takeover because they bypass the organization's standard authentication controls. Leaving a recovery path unavailable increases the

Documentation	Updates
	risk of unauthorized account access and loss of control over who can regain entry to affected accounts. • Functional impact ○ (Old) <blank> ○ (New) Enabling this control doesn't disable SSO. It requires that an account-recovery path exist and restricts write access on a recovery-authenticated session to SSO- and recovery-related properties only. Admin users that have never configured account recovery, or that have zero users enrolled, will be blocked from turning on Multi-SSO until at least one user opts in. Users may test the Multi-SSO activation flow and the account-recovery login flow when removing or disabling ACR-enrolled users. • Data type ○ (Old) <blank> ○ (New) Boolean • Default value ○ (Old) <blank> ○ (New) true

	• (Old) <blank> • (New) true
Timeout guest sessions	• Description ○ (Old) Use the glide.guest.session_timeout system property to control the inactive session timeout for unauthenticated users. By default, the value of this property is 30 minutes. If there are availability concerns from persisting too many sessions in memory, the value of this property can be lowered to 5. Avoid setting this property greater than 30, as large timeout values increase the number of sessions persisted by the instance, and may cause minor availability concerns. Avoid setting this property greater than 30. Large timeout values increase the number of sessions persisted by the instance, and may cause minor availability concerns. ○ (New) The *glide.guest.session_timeout* property controls the inactive session timeout for unauthenticated (guest) users, specified in minutes. New instances are provisioned with a default of 5 minutes. If the property does not exist in the sys_properties table, the effective value defaults to 0. When set to 0, the guest-specific override is turned off and the session instead uses the general UI session timeout (*glide.ui.session_timeout*). Setting the *glide.guest.session_timeout* property greater than 30 minutes increases the number of sessions persisted by the instance, which may cause minor availability concerns. • Remediation

Documentation	Updates
	active guest HTTP sessions, regardless of the session activity. The configured value is in minutes. A value of zero disables the lifespan limit entirely, allowing sessions to persist indefinitely until the inactive timeout fires. Guest users are unauthenticated users who access the instance without logging in. • Rule script: Script has been updated to improve detection accuracy • Functional impact ○ (Old) <blank> ○ (New) Guest HTTP sessions that exceed the configured lifespan are silently invalidated and reissued a new session ID. The guest user sees no error or logout screen, but any session-scoped state (for example, in-progress form data, embedded portal widget context, or session-based rate limiting) accumulated during that session is lost and starts fresh. Legitimate guest users on long-running but otherwise idle browser tabs may need to reload the page after the configured interval elapses. • Dependencies and prerequisites ○ (Old) <blank> ○ (New) This control interacts with the *glide.guest.session_timeout* property, which controls the guest idle-session timeout duration. The platform requires the active session maximum lifespan to be greater than or equal to the idle timeout. If the active session lifespan is configured to a value lower than the idle-session timeout, the platform automatically increases the effective lifespan to match the idle-session timeout and logs a warning message. • Data type ○ (Old) <blank> ○ (New) integer

	request over TLS has its certificate checked for revocation using OCSP or CRL, as governed by the other properties in this family. When this property is set to "false", no revocation checking is performed at all for outbound TLS connections, regardless of how the other certificate-revocation properties are configured. • Data type ○ (Old) <blank> ○ (New) Boolean • Default value ○ (Old) <blank> ○ (New) true
Honor admin override ACLs	• Description ○ (Old) ACLs are evaluated cumulatively. If there are a number of ACLs on any given field and the Admin Overrides option is false (not selected) on one of them, then the effective admin overrides for all the ACLs are considered to be false. This causes admins to be unable to pass even the ACL where the override should be in effect. If "glide.security.admin.override.accessterm" is not set to the recommended value of "true" then, even if one of the ACL terms under the ACL rule is "Admin overrides" false, the entire rule evaluates to false. ○ (New) The "glide.security.admin.override.accessterm" property controls how the platform decides whether an administrator can bypass an access rule when a resource (a table, a field) has more than one access rule applied to it. Each individual access rule can be configured to grant or deny

Documentation	Updates
	an admin override on its own. When this property is set to its recommended value of true, the per-rule setting is honored individually. A rule explicitly configured to deny an admin override still blocks the administrator even if another rule on the same resource permits one. When set to "false", the bypass decision is instead made at a broader, combined level. This can let an administrator through even though one of the applicable rules was specifically configured to block the override. • Security risk ○ (Old) ACLs with conflicting "Admin overrides" settings may cumulatively evaluate to false, potentially preventing administrators from accessing fields they should have access to and inadvertently causing denial of access to critical data. ○ (New) When access checks are evaluated coarsely, a privileged user can access a resource despite rules set to deny override. This allows the most restrictive protection to be ignored in favor of a more permissive rule on the same resource. Protected data can be set to readable or writable, risking unauthorized access to sensitive information. • Functional impact ○ (Old) <blank> ○ (New) Changing this property to true affects only elevated-admin access decisions on resources governed by more than one access rule; regular users and single-rule resources see no behavior change. After the change, test contextual security scenarios where an admin role is granted access to a field or record through multiple layered rules, confirming that a rule explicitly configured to deny override still blocks the admin as expected. No

Documentation	Updates
	○ (New) Authenticated UI sessions that exceed the configured lifespan are explicitly logged out. The session cookies are cleared and the session is invalidated, forcing the user to re-authenticate, rather than silently reissuing a new session ID as occurs with guest and integration sessions. Users must re-authenticate to continue working, even if they were actively using the platform when the session expired. • Dependencies and prerequisites ○ (Old)<blank> ○ (New) This control interacts with the "glide.ui.session_timeout" property, which controls the UI idle-session timeout duration. The platform requires the active session maximum lifespan to be greater than or equal to the idle timeout. If the active session lifespan is configured to a value lower than the idle-session timeout, the platform automatically increases the effective lifespan to match the idle-session timeout and logs a warning message. • Default value ○ (Old)<blank> ○ (New) 0
Require authorization for import requests	Default value • (Old)<blank> • (New) true
Enforce password reset on API requests	Default value • (Old)<blank> • (New) true
Disable external content URL	Default value

	• (Old)<blank> • (New) false
Enforce security rules to sharing dashboards	Default value • (Old)<blank> • (New) false
Require authorization for unload requests	Default value • (Old)<blank> • (New) true
Disable adding default roles to skill ACLs	Functional impact • old Certain roles may be prevented from using skills if they do not satisfy an existing access control. These two property configurations will ensure certain roles always retain a base level of access to all skills. • New When the com.glide.one_extend.include_default_roles_for_skill_acl property is set to false, roles are no longer automatically granted access to generative AI skill ACLs — any role that needs to execute a skill must satisfy the skill's own access control instead of relying on an automatically-added default role. The related "com.glide.one_extend.default_roles_for_skill_acl" property, which lists which roles get auto-added when com.glide.one_extend.include_default_roles_for_skill_acl is set to true, has no effect while it is set to false.
Require authorization for XML requests	Default value

Documentation	Updates
Disable legacy JQuery behavior	• Description ○ (Old) <blank> ○ (New) If "glide.jquery.legacy" is not set to the recommended value of "false", then older prepatched JQuery versions are used which will introduce unpatched vulnerabilities in the library. When false, integrates the JQuery 1.12.3 and 2.2.3 security patches. The system property is a failsafe in case any organizations depend on the non-patched versions of angularJS to run their custom implementations. • Security Risk ○ (Old) <blank> ○ (New) This could potentially lead to security risks arising from attacks on vulnerabilities discovered in outdated JQuery library versions.
Enforce Query ACLs for SubLists, List Counts and Widget Data Tables	Rule Script updated to improve detection accuracy.
Enable antivirus scan	• Description ○ (Old) <blank> ○ (New) If "com.glide.snap.enable_scan" is not set to the recommended value of "true", then antivirus scanning is disabled. • Security Risk ○ (Old) <blank> ○ (New) Users may download malicious files leading to desktop and session compromise.
Timeout guest sessions	• Description ○ (Old) Control the inactive session timeout for unauthenticated users with the

Documentation	Updates
	"glide.guest.session_timeout" system property. Raise the value of this property to extend the period of time your instance persists sessions beyond the default of 30 minutes. Avoid excessively large timeout values, which can increase the number of sessions persisted by the instance, and cause minor availability concerns. ○ (New) Use the glide.guest.session_timeout system property to control the inactive session timeout for unauthenticated users. By default, the value of this property is 30 minutes. If there are availability concerns from persisting too many sessions in memory, the value of this property can be lowered to 5. Avoid setting this property greater than 30, as large timeout values increase the number of sessions persisted by the instance, and may cause minor availability concerns. • Remediation ○ (Old) Ensure the Glide Property 'glide.guest.session_timeout' is set to a default value of 30. It may be desirable to lower this value to 5 in rare cases of availability concerns on the instance. ○ (New) Ensure the Glide Property 'glide.guest.session_timeout' is configured to the default value of 30. In the rare case there are availability concerns from persisting too many sessions in memory, the value of this property can be lowerered to 5. • Security Risk ○ (Old) Large timeout values can increase the number of concurrent sessions on your instance, causing minor availability concerns. ○ (New) Avoid setting this property greater than 30. Large timeout values increase the

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	○ (Old) <blank> ○ (New) The milliseconds delay limits the ability of a malicious actor to attempt to guess users identification or verification details, by using automation tools ("bots").
Prevent inactive users from logging in	• Description ○ (Old) <blank> ○ (New) When the Glide Property 'glide.authenticate.only.allow.active.user.login' is not set to 'true', users in the sys_user table marked inactive can still login to the instance. Users may be marked inactive if they no longer have permission to login (such as during termination from a company). • Security Risk ○ (Old) <blank> ○ (New) Inactive users may still access the instance and any data they could previously access.
Enable High Security plugin	• Description ○ (Old) <blank> ○ (New) The High Security plugin, activated by default, creates more than 900 different configurations to control the level of security on your instance. These configurations enable strict access control, input validation, and output encoding. It separates user functionality from access control management functionality through requiring administrators to explictly elevate into a "security_admin" role before making access control changes. • Security Risk

Documentation	Updates
	○ (Old) <blank> ○ (New) Critical parts of the instance may be exposed to unauthorized access or manipulation.
Activate Limit Concurrent Sessions Plugin	• Short Description ○ (Old) Limit Concurrent Sessions Plugin ○ (New) Activate Limit Concurrent Sessions Plugin • Description ○ (Old) <blank> ○ (New) The Limit Concurrent Sessions plugin (com.glide.limit.concurrent.sessions) allows an administrator to limit the number of active sessions per user/role. It is recommended this plugin be enabled and configured to reduce the likelihood of session hijacking. If this plugin is enabled and configured, there will be a limit to the number of open sessions that can be hijacked. • Security Risk ○ (Old) <blank> ○ (New) Higher numbers of active concurrent sessions creates security risk by increasing the attack surface for account compromise, making it harder to detect unauthorized access and enforce session accountability across devices and locations. • Plugin Applicability ○ (Old) Limit Concurrent Sessions Plugin ○ (New) <blank>

Documentation	Updates
Proactively invalidate sessions after defined durations	• Short Description ○ (Old) Proactively Invalidate Inactive Sessions ○ (New) Proactively Invalidate Sessions After Defined Durations • Description ○ (Old) <blank> ○ (New) When glide.active.session.timeout.invalidate.session isnot set to true, there's a small interval of time where a timed-out session isn't invalidated proactively before the Tomcat container invalidates the session. The duration of this time interval is dependent on additional properties representing differing use cases. glide.ui.active.session.life_span: The value of this property defines the time, in minutes, before a UI session is invalidated. glide.guest.active.session.life_span: The value of this property defines the time, in minutes, before a guest session is invalidated. glide.integrations.active.session.life_span: The value of this property defines the time, in minutes, before an integrations session is invalidated. • Remediation ○ (Old) Ensure the Glide Property 'glide.active.session.timeout.invalidate.session' exists and is set to the value 'true'. If the property does not appear in the sys_properties table, add a new record. ○ (New) Ensure that the property "glide.active.session.timeout.invalidate.session" is set to true. • Security Risk

Documentation	Updates
	○ (Old) <blank> ○ (New) If a session is hijacked, an attacker may be able to use a session during this small period.
Enable policy based session access for mobile	• Description ○ (Old) <blank> ○ (New) The Zero Trust - Policy Based Session Access plugin allows security admins to reduce user access in a session based on IP, Location, Identity provider attributes and user attributes using adaptive authentication policies. When this property is enabled (set to 'true'), then users logging in via mobile device will have their roles restricted as configured by the plugin policies. • Security Risk ○ (Old) <blank> ○ (New) Instance admins may wish to restrict high privileged access when users login via mobile device, possible indicating an unsafe environment for sensitive operations.
Enable work order management query rules for service organizations	• Description ○ (Old) <blank> ○ (New) When set to 'true', rules/filters from sn_query_rule table will be used to determine read access to Field Service Management-related tables (Work Order and Work Order Task) to the logged in user through query business rules and read ACLs. When 'false', the records won't be filtered based on query rules. Query business rules add additional security validations. Specifically, this property will filter records for agents, qualifiers, and dispatchers based on their assigned territory or

Documentation	Updates
	territory membership. It is best practice to follow the principle of least privilege when reading records. • Security Risk ○ (Old) <blank> ○ (New) There may be increased risk of data exposure from Field Service Management tables.
Disable SQL error messages	• Description ○ (Old) <blank> ○ (New) If "glide.db.loguser" is not set to the recommended value of "false", then sensitive server-side error messages could be displayed to end-users. Error messages can include stack traces and information about the structure of the database that could provide an attacker the knowledge needed to perform successful SQL Injection should the preconditions exist. • Security Risk ○ (Old) <blank> ○ (New) Messages can include stack traces and database structure details, which attackers can leverage to craft targeted SQL injection attacks if other vulnerabilities exist. Exposing internal error information increases the risk of exploitation.
Set guest user for soap requests	• Description ○ (Old) <blank> ○ (New) Use the com.glide.soap.guest_user glide property to control the access level of unauthenticated SOAP requests. If this property isn't set to the recommended value of soap.guest or is set to a user with limited privileges, then SOAP requests execute on behalf of this user.

Documentation	Updates
	• Remediation ○ (Old) Ensure the property "com.glide.soap.guest_user" is set to "soap.guest". ○ (New) Ensure the property is set to soap.guest to ensure an appropriate level of access for unauthenticated SOAP requests. • Security Risk ○ (Old) <blank> ○ (New) Unauthenticated SOAP requests can allow unauthorized access if not properly restricted. Evaluating these requests against a minimally privileged user helps reduce the risk of exposing sensitive operations. Failure to enforce this control may result in elevated access and compromise system integrity. • Functional Impact ○ (Old) <blank> ○ (New) SOAP requests are restricted to the permissions of the soap.guest user. If an integration relies on a resource that does not have the appropriate ACLs for soap.guest, those requests will result in permission denials. • Data Type ○ (Old) <blank> ○ (New) String User ID (user_name) of a user in the sys_user table • Out of Box Value ○ (Old) <blank> ○ (New) soap.guest

Documentation	Updates
Required JMS connection factories	• Description ○ (Old) <blank> ○ (New) This property controls the Java Messaging Service (JMS) connection factories that the MID Server can use. It is intended for a few select factories needed by plugins for JMS activity or action. Including additional factories could be a step in a chain of attack for vulnerabilities such as JNDI insertion that rely on capabilities an attacker can leverage in allowed factories. To prevent the possibility of any leveraged vulnerability, do not include factories beyond the necessary defaults. • Security Risk ○ (Old) <blank> ○ (New) Expanding the set of Java Messaging Service (JMS) connection factories beyond the necessary defaults introduces a significant risk because it increases the attack surface for exploitation techniques such as JNDI injection. Allowing additional factories can enable attackers to leverage insecure configurations or vulnerabilities in messaging components as part of a broader attack chain, potentially leading to remote code execution or system compromise. Restricting factories to only those required by core functionality is essential to maintain a secure posture.
Require obfuscation of mobile app UI	• Description ○ (Old) <blank> ○ (New) If "glide.sg.blur_ui_when_backgrounded" is not set to the recommended value of "true", then the mobile app's UI is visible when viewed from the app switcher once the app has been backgrounded. • Security Risk ○ (Old) <blank> ○ (New)

Documentation	Updates
	Blurring mobile backgrounding screenshots provides a higher level of confidentiality and privacy on the local device by blurring this view when backgrounded.
Enforce device encryption and passcode requirements [New in Security Center 1.3]	• Description ○ (Old) <blank> ○ (New) When the Glide Property 'glide.sg.device_encryption_enabled' is set to true, the ServiceNow mobile app will check that device encryption is enabled and that device passcode is enabled. If encryption or passcode is not enabled, the user will not be allowed to log into the instance on mobile. This property enforces FIPS 140-2 Encryption. Mobile device encryption and passcode are important security features for ensuring an unauthorized user cannot access the content of the device even if the device is physically obtained. • Security Risk ○ (Old) <blank> ○ (New) This creates a risk that sensitive data stored or accessed through the mobile app could be exposed if the device is lost, stolen, or compromised. Without encryption and passcode enforcement, unauthorized users can gain physical access to confidential information, undermining compliance with FIPS 140-2 and weakening overall data protection.
Enable protected tables plugin	• Description ○ (Old) <blank> ○ (New) When the Glide Property 'com.glide.security.protected_table.enabled' is set to 'true', The Protected Tables plugin will be utilized to prevent higher privilege users on an instance from tampering with log tables. The following logging tables will have special protections

Documentation	Updates
	when this property is set to 'true': syslog (config not modifiable) syslog_transaction sys_outbound_http_log sysevent sys_audit sys_push_notification protected_table_configuration (config not modifiable) syslog_app_scope • Security Risk ○ (Old) <blank> ○ (New) Log integrity must be maintained to allow discovery of malicious activity.
Enforce read ACLs on report views	• Description ○ (Old) <blank> ○ (New) The property "glide.report.report_view.read_acl", when set to "enforce", enforces the READ ACL (table level) on reporting functions when there is no Report View ACL on the table/field. • Security Risk ○ (Old) <blank> ○ (New) ACLs could be bypassed, leading to potential sensitive information disclosure.
Restrict access to GlideSystemUserSession scriptable API	• Description ○ (Old) <blank> ○ (New) The methods "gs.addErrorMessageNoSanitizationMessaging()" and "gs.addInfoMessageNoSanitization()" are used within the scripting environment for logging and notifications. Both of these are available in the sandbox if this property is not set to the recommended value of "false". The sandbox is a low privileged scripting environment available to unauthenticated and no role users. Both of these methods can be used to display unsanitized input to a user. • Security Risk

Documentation	Updates
	○ (Old) <blank> ○ (New) Displaying unsanitized input to the user is dangerous, as unsanitized input may contain dangerous code that runs in the user's browser. This can be utilized for traditional reflected XSS attacks. Reflected XSS attacks can be used in multiple scenarios, including session hijacking.
Enable SMS code notification for enrollment and verification	• Description ○ (Old) <blank> ○ (New) This property "password_reset.sms.use_notify" controls usage SMS code notification for enrollment and verification. If "password_reset.sms.use_notify" is set to the recommended value "true", then user will be notifed for password reset for SMS verification method and new device enrollment. Using SMS code notification for enrollment and verification is more secure that default email notification. • Remediation ○ (Old) Ensure the property "password_reset.sms.expiry" is set to "true". ○ (New) Ensure the property "password_reset.sms.use_notify" is set to "true". • Security Risk ○ (Old) <blank> ○ (New) Email-based notifications are generally less secure because they are more susceptible to account compromise and phishing attacks. Using SMS for verification provides stronger assurance

Documentation	Updates
	of user identity and reduces the risk of unauthorized password resets or fraudulent device enrollments.
Do not use demo certificates for active SAML configurations	• Description ○ (Old) <blank> ○ (New) The demo certificates provided by ServiceNow should not be used in production SAML configurations. The certificates are common among all instances with known passphrase. If one of the SAML properties utilizing a certificate keystore is active (require_signed_authnrequest, require_signed_logoutrequest or encrypt_assertion) then the demo data must not be used. Since demo data is shared among all instance, there is no integrity garuntee of requests signed with shared certificates. • Security Risk ○ (Old) <blank> ○ (New) Messages encrypted by the IDP could be decrypted by any actor, if intercepted.
Disable email OTP for multi-factor authentication	• Description ○ (Old) <blank> ○ (New) The property "glide.authenticate.multifactor.email.otp.enabled" controls if a token for the second authentication factor can be sent via email. Email is considered a weak MFA factor which an attacker is more likely to gain access into for defeating MFA. If the property is false: 1. The user will not see email OTP option on the MFA validation screen. If the property is true: 2. The email factor is shown in cases where the email factor policy is inactive and no other 2fa registered. 3. The email factor is shown if the email factor policy is

Documentation	Updates
	active and evaluated to true. 4. The email factor is not shown if the email factor policy is active and evaluated to false. • Security Risk ○ (Old) <blank> ○ (New) An attacker may successfully bypassing MFA when they have the user's password.
Enable UserCookie version 3.1	• Description ○ (Old) <blank> ○ (New) UserCookie v3 is generated only when property glide.ui.secure.cookies.use_kmf is disabled. UserCookie v3 is not secure due to storing secret key for HMAC in source code and identical for all customers. By setting the property "glide.ui.secure.cookies.use_kmf" to "true" UserCookie v3.1 will be used and secret key will be stored in security storage such as KMF. • Security Risk ○ (Old) <blank> ○ (New) This creates a significant risk of session hijacking, as attackers who obtain or reverse-engineer the key can forge authentication cookies and impersonate users.
Enable Jelly JS interpolation protection for nested expressions	• Description ○ (Old) <blank> ○ (New) This property allows a customer to turn on or off interpolation protection specifically for nested Jelly expressions. Interpolation protection ensures that when Jelly expressions are used in JavaScript, they must be deemed safe by either falling under certain categories OR being marked as SAFE in the expression itself. This property was added to

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	protect against possibly dangerous Jelly expressions which are nested in another Jelly expression. • Security Risk ○ (Old) <blank> ○ (New) Unprotected interpolated jelly expression may result in a malicious actor sending a crafted GET parameter to a Jelly page and cause the contents of that parameter to be evaluated as server-side JavaScript with admin privileges. • Data Type ○ (Old) <blank> ○ (New) Boolean • Out of Box Value ○ (Old) <blank> ○ (New) true
Escape XML markup	• Description ○ (Old) <blank> ○ (New) This property escapes XML values at the parser level for the user interface. It prevents reflected and stored cross-site scripting attacks. This property is not applicable in Service Portal. • Security Risk ○ (Old) <blank> ○ (New) If "glide.ui.escape_text" is not set to the recommended value of "true", then XML values will not be escaped at the parser level for the user interface; this will leave jelly templates susceptible to reflected and stored cross site scripting attacks.

Documentation	Updates
Disable GlideRecord scope fencing legacy behavior	• Description ○ (Old) <blank> ○ (New) GlideRecord provided cross scope create/update access to tables that were not configured with that level of access. In order to prevent customers from having applications broken when this scoped access behavior was patched, the property glide.record.legacy_cross_scope_access_policy_in_script was created. When 'true', cross scope access falls back onto legacy behavior (insecure). This property disables scope fencing, allowing scoped apps to access global script interfaces. • Security Risk ○ (Old) <blank> ○ (New) It is best security practice to have scope fencing restrictions in place. Scoping ensures applications can only access resources with explicit access or within their scope, following the principle of least privilege. Disabling this feature could lead to confidentiality, availability, and integrity impacts.
Remove remember me	• Description ○ (Old) <blank> ○ (New) This property controls the Remember Me check box from the login page to prevent login information from being cached when set to true. If the value is set to false, caching of authentication information is allowed and the "Remember Me" checkbox is displayed. • Security Risk ○ (Old) <blank> ○ (New)

Documentation	Updates
	This increases the risk of unauthorized access if the device is shared, lost, or compromised, as cached credentials can allow attackers to bypass authentication.
Disable outbound SSLv2/SSLv3 connections	• Description ○ (Old) <blank> ○ (New) This property controls the desired transport encryption protocol. If "glide.glide.outbound.sslv3.disabled" is not set to the recommended value of "true", then outbound MID server connections such as REST and SOAP requests will use SSL as the transport protocol. SSL was proven to be insecure in 2014. • Security Risk ○ (Old) <blank> ○ (New) SSLv3 has been proven insecure since 2014 due to vulnerabilities like POODLE, making it susceptible to man-in-the-middle attacks and data interception. Allowing SSLv3 undermines transport encryption and exposes sensitive data in transit, violating modern security standards.
Disable creating users from incoming emails	• Description ○ (Old) <blank> ○ (New) An administrator can set an email property to automatically create users from incoming emails. If set this property to the insecure value, the instance will automatically create users from incoming email. Each user created will have the same hardcoded default password which makes bypassing authentication through brute force easier. • Security Risk ○ (Old) <blank> ○ (New)

Documentation	Updates
	Allowing automatic user creation without strong password controls undermines authentication security and increases the likelihood of system compromise.
Minimize SMTP Recipient Quantity	• Description ○ (Old) <blank> ○ (New) This property specifies the maximum number of recipients the instance can list in the To: line for a single email notification. Notifications that would exceed this limit instead create duplicate email notifications addressed to a subset of the recipient list. Each email notification has the same maximum number of recipients. • Security Risk ○ (Old) <blank> ○ (New) This can lead to resource exhaustion and potentially cause a Denial of Service (DoS) condition on the email subsystem or the instance itself. Limiting recipient counts is essential to prevent abuse and maintain system performance and availability.
Enable password reset policy checks	• Description ○ (Old) <blank> ○ (New) Use the glide.enable.password_policy property to customize password strength validation rules for the Change Password form. Customize the length and complexity values to match your organization's security policy. If "glide.enable.password_policy" is not set to the recommended value of "true", then password standards will not be enforced. • Security Risk

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	○ (Old) <blank> ○ (New) Enforcing password complexity is critical to maintaining strong authentication and reducing exposure to account takeover.
Clear pasteboard when app backgrounds	• Description ○ (Old) <blank> ○ (New) The "glide.sg.clear_pasteboard_when_backgrounded" property controls if text copied from ServiceNow mobile app is kept in the clipboard and pasteboard after the app is in background mode. • Security Risk ○ (Old) <blank> ○ (New) This creates a risk of sensitive information disclosure, as clipboard data can be accessed by other applications on the device, potentially exposing credentials, PII, or confidential business data. Enforcing this property helps prevent unintended data leakage across apps.
Restrict permissions for CMDB model	• Description ○ (Old) <blank> ○ (New) This property is an additional access control to the CMDB model. If "csm_cmdb_model.customer_visible_flag" is not set to the recommended value of "true", then any user with the sn_esm_user role and out of the box ACLs will have permissions to the CMDB model. Note that this role tends to be granted to external users. • Security Risk

Documentation	Updates
	○ (Old) <blank> ○ (New) External users could unwillingly be given permissions to the CMDB model.
Disable JavaScript tags in embedded HTML	• Description ○ (Old) <blank> ○ (New) If "glide.ui.security.codetag.allow_script" is not set to the recommended value of "false", then this property allows rendered HTML in journal fields and forms which opens room for XSS attacks. Malicious HTML needs to be put between code tags for example [code][/code]. • Security Risk ○ (Old) <blank> ○ (New) Uncontrolled JavaScript risks Cross-Site Scripting (XSS) attacks, enabling malicious actors to inject and execute harmful scripts in the user's browser. Such attacks can lead to session hijacking, credential theft, and compromise of sensitive data.
Restrict performance monitoring access	• Description ○ (Old) <blank> ○ (New) If "glide.security.diag_txns_acl" is not set to the recommended value of "true", then All users (authenticated or not) have access to diagnostic pages such as stats.do, xmlstats.do, threads.do and replication.do pages. These endpoints are intended to be used for monitoring instance health. • Security Risk

Documentation	Updates
	○ (Old) <blank> ○ (New) Information exposed by performance monitoring endpoints may be useful to attackers.
Configure service portal widgets table allow list	• Description ○ (Old) <blank> ○ (New) The Glide Property 'glide.service_portal.widget.table_allow_list' contains the list of tables allowed to be accessed by unauthenticated users through Service Portal widgets that make use of the additional security checks provided in the SNCACLWidgetUtil script include. This property is only enforced if the Glide Property 'glide.service_portal.widget.enforce_public_check' is 'true'. There may be unauthenticated information disclosure if unnecessary tables are listed in this property. Table ACLs will still be evaluated as previously occurred. • Security Risk ○ (Old) <blank> ○ (New) Unauthenticated users may gain access to sensitive data through Service Portal widgets, potentially leading to information disclosure despite existing table ACLs. • Fallback Value ○ (Old) <blank> ○ (New) ''
Honor admin override ACLs	• Description ○ (Old) <blank> ○ (New) ACLs are evaluated cumulatively. If there are a number of ACLs on any given field and the Admin Overrides option is false (not selected) on one of them, then the

Documentation	Updates
	effective admin overrides for all the ACLs are considered to be false. This causes admins to be unable to pass even the ACL where the override should be in effect. If "glide.security.admin.override.accessterm" is not set to the recommended value of "true" then, even if one of the ACL terms under the ACL rule is "Admin overrides" false, the entire rule evaluates to false. • Security Risk ○ (Old) <blank> ○ (New) ACLs with conflicting "Admin overrides" settings may cumulatively evaluate to false, potentially preventing administrators from accessing fields they should have access to and inadvertently causing denial of access to critical data.
Require XMLdoc2 entity validation with allowlist	Short Description • (Old) Require XMLdoc2 entity validation with allowlistDisable Entity Expansion • (New) Require XMLdoc2 entity validation with allowlist
Enforce oauth state parameter validation	• Description ○ (Old) <blank> ○ (New) The "glide.oauth.state.paramater.required system" property enables the "State" parameter to be required in an OAuth request for authorization code flow. Beginning in the Madrid release, the system property "glide.oauth.state.parameter.required" adds a "State" parameter for an OAuth request. For zbooted instances, the property is true. For upgraded instances, the property is not present, so the "State" parameter is not enabled. The "State" parameter is a string value, and should not contain special characters. The State parameter cannot be empty or " ". Not

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	enabling the "State" parameter to "true" ensures that an attacker cannot perform CSRF attacks during authentication can allow an attacker to perform operations as the victim. • Security Risk ○ (Old) <blank> ○ (New) Not enabling the glide.oauth.state.parameter.required property in OAuth authorization code flow increases the risk of Cross-Site Request Forgery (CSRF) attacks, potentially allowing attackers to impersonate users and perform unauthorized actions.
Limit max comments per user per day	• Description ○ (Old) <blank> ○ (New) If "sn_kb_social_qa.max_comments_per_user_daily" is not set to the recommended value of "500" or less, then there will be no restriction on number of QA comments per day. • Security Risk ○ (Old) <blank> ○ (New) Too many comments could lead to resource exhaustion.
#unique_313	• Description ○ (Old) <blank> ○ (New) If "glide.cs.debug" is not set to the recommended value of "false", then chat server messages logging is enabled. Setting the property value to true enables logging chat server messages on system logs. As a lot of log messages are generated, it is advised to enable it only when troubleshooting chat server. After troubleshooting, the property should be disabled to avoid clogging system logs.

Documentation	Updates
	Setting the property to false, which is also the default value does not log chat server messages on system logs. • Security Risk ○ (Old) <blank> ○ (New) This could lead to unintended sensitive information leak through system logs.
Configure service portal widgets allow list	• Description ○ (Old) <blank> ○ (New) The Glide Property 'glide.service_portal.widget.allow_list' determines the list of widgets that are allowed to attempt to access any table on the instance. ACLs for those tables will still be enforced. If there are misconfigured empty ACLs on tables on the instance, widgets in this list may allow access to those tables, leading to information disclosure. This property is only enforced if the widget makes use of SNCACLWidgetUtil, and the Glide Property 'glide.service_portal.widget.enforce_public_check' is set to 'true'. • Security Risk ○ (Old) <blank> ○ (New) Unauthenticated users may gain unintended access to sensitive table data via Service Portal widgets, resulting in potential information disclosure. • Fallback Value ○ (Old) <blank> ○ (New) ''
Minimize external user registration link expiration duration	• Description ○ (Old) <blank> ○ (New)

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	If "sn_ext_usr_reg.Reg_link_expiration_days" is not set to the recommended value of "3", then a registration link could be used by someone other than the intended user if the link is discovered later in time. • Security Risk ○ (Old) <blank> ○ (New) Longer expiration windows weaken account provisioning security and create opportunities for unauthorized account creation or impersonation.
Prevent verbose HTTP request logging	Description • (Old) The two properties glide.outbound_http_log.override and glide.outbound_http_log.override.level work together to control the level of logging for outbound HTTP requests. When glide.outbound_http_log.override is set to "true", the log level for requests and responses is controlled by glide.outbound_http_log.override.level . If the override level is set to "all" or "elevated", then request and response headers are logged • (New) The two properties glide.outbound_http_log.override and glide.outbound_http_log.override.level work together to control the level of logging for outbound HTTP requests. When glide.outbound_http_log.override is set to "true", the log level for requests and responses is controlled by glide.outbound_http_log.override.level . If the override level is set to "all" or "elevated", then request and response headers are logged

Documentation	Updates
Enable CAPTCHA for external user registration	• Description ○ (Old) <blank> ○ (New) If "sn_ext_usr_reg.captchaEnabled" is not set to the recommended value of "true", then CAPTCHA will not be validated for external user registration and could lead to automatic account creation attacks. • Security Risk ○ (Old) <blank> ○ (New) Enforcing CAPTCHA is critical to prevent bot-driven attacks and maintain the integrity of user onboarding.
Apply domain separation on dot walked fields	• Description ○ (Old) <blank> ○ (New) This property controls whether join queries are given domain separated conditions or not, in order to ensure they apply domain separation functionality for dot walked fields. • Security Risk ○ (Old) <blank> ○ (New) Sensitive information could be disclosed that is not to be shared with a specific domain. • Functional Impact ○ (Old) <blank> ○ (New) There may be moderate functional impact to the instance if components are reliant on the unsafe cross domain queries. Instances should be tested in non-production environments before enabling.

Documentation	Updates
Disable unauthenticated published reports	• Description ○ (Old) <blank> ○ (New) If "glide.report.published_reports.enabled" is not set to the recommended value of "false", then reports stored on the instance can be made visible without authentication. • Security Risk ○ (Old) <blank> ○ (New) Allowing unauthenticated access to sensitive data can cause inadvertent information disclosure to a malicious actor.
Require authorization for JSONv2 request	• Description ○ (Old) <blank> ○ (New) If "glide.basicauth.required.jsonv2" is not set to the recommended value of "true", then this will disable Basic Authentication for JSONv2 format export processor. This also happens when combined with a wrong role within the guest_user related property (For example a high privileged user such as Admin). • Security Risk ○ (Old) <blank> ○ (New) Unauthenticated access to JSON export data, when combined with misconfigured guest user role, poses a significant risk of unauthorized data exposure.
Require authorization for XML output requests	• Description ○ (Old) <blank> ○ (New) If "glide.basicauth.required.xmloutputprocessor" is not set to the recommended value

Documentation	Updates
	of "true", then basic authorization is not required for all inbound XMLOutputProcessor requests. This could lead to unauthenticated information disclosure from the instance. • Security Risk ○ (Old) <blank> ○ (New) Unauthenticated access to XML export data, when combined with misconfigured guest user role, poses a significant risk of unauthorized data exposure.
Minimize reset password SMS expiry duration	• Description ○ (Old) <blank> ○ (New) The property "password_reset.sms.expiry" denotes the number of minutes before the SMS code expires. • Security Risk ○ (Old) <blank> ○ (New) If the value is too high, an attacker may guess the SMS code to reset the password.
Prevent Unauthenticated Access to Virtual Agent Embedded Web Client	• Description ○ (Old) <blank> ○ (New) The UI page sn_va_web_client_app_embed , which is an embedded web client for Virtual Agent, contains the ACL marked 'true' in the sys_public table Out of Box. It has been confirmed that there are use cases where public accessibility is needed however this is not a security best practice to set it to default publicly accessible. • Security Risk

Documentation	Updates
	○ (Old) <blank> ○ (New) Sensitive information may be exposed to unauthenticated users.
Maximize reset password SMS pause window duration	• Description ○ (Old) <blank> ○ (New) If "password_reset.sms.pause_window" is not set to the recommended value of "2" minutes or greater, then a malicious user could initiate many password reset SMS codes in a brief window of time. • Security Risk ○ (Old) <blank> ○ (New) This increases the attacker's likelihood of predicting the SMS reset code.
Maximize reset password request retry window duration	• Description ○ (Old) <blank> ○ (New) The property "password_reset.request.retry_window" specifies the length of time before the count for password reset attempts refreshes. • Security Risk ○ (Old) <blank> ○ (New) If the value is too low, then it will make brute forcing against password reset process attacks much faster.
Double check inbound transactions	• Description ○ (Old) <blank> ○ (New) Property provides an extra layer of security on form submission / field updates by ensuring only users with the

Documentation	Updates
	proper permissions are allowed to update a form. If "glide.security.strict.updates" is not set to the recommended value of "true", then updates are not strict meaning they are able to modify fields visible to them regardless of whether they have the appropriate permissions. • Security Risk ○ (Old) <blank> ○ (New) Users may be able to update form fields simply by having visibility into them—regardless of their actual permissions—creating a risk of unauthorized data modification and privilege escalation.
Minimize reset password request expiration duration	• Description ○ (Old) <blank> ○ (New) If "password_reset.request.expiry" is not set to the recommended value of "10" or less, then it increases the opportunity for someone else to guess and use the request and attempt to reset the password. • Security Risk ○ (Old) <blank> ○ (New) Short expiration windows are critical to reducing the opportunity for unauthorized password resets and maintaining account security.
Limit Invalid Password Reset Attempts	• Description ○ (Old) <blank> ○ (New) The property "password_reset.request.max_attempt" dictates the maximum number of unsuccessful password reset attempts that can be taken before the user is locked out of password

Documentation	Updates
	reset process. The lockout period is determined by the value in "password_reset.request.max_attempt_window". • Security Risk ○ (Old) <blank> ○ (New) If the value is too high, then it could be possible to perform brute force attack against password reset process.
Enable CAPTCHA in password reset	• Description ○ (Old) <blank> ○ (New) If "password_reset.captcha.ignore" is not set to the recommended value of "false", then a CAPTCHA challenge-response will not be used during the password reset process. CAPTCHAs help prevent automation attacks by prompting the user for a challenge-response that is not easily answered by automated systems. • Security Risk ○ (Old) <blank> ○ (New) If the CAPTCHA is disabled, an attacker may be more successful during automated attacks against the password reset feature.
Validate remote host	• Description ○ (Old) <blank> ○ (New) If "glide.update_set.remote.check_host" is not set to the recommended value of "true", then the Team Development Remote Instance test feature will allow an internal network port scan by providing positive/negative error messages. • Security Risk ○ (Old) <blank> ○ (New)

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
Enforce production instance behavior	• Description ○ (Old) <blank> ○ (New) If "glide.installation.production" is not set to the recommended value of "true", then the instance is not treated as a production instance, permitting zboot and other potentially dangerous scripts. • Security Risk ○ (Old) <blank> ○ (New) Allowing a production instance to be evaluated as non-production can lead to information disclosure or denial of service.
Enforce security rules to sharing dashboards	• Description ○ (Old) <blank> ○ (New) When the Glide Property 'glide.cms.dashboards.sharing_with_secure_search' is not set to 'true', a user can share a dashboard to groups and roles that they do not personally have access to. This property enforces ACLs on searching the sys_user, sys_user_role, and sys_user_group tables when sharing a dashboard. • Security Risk ○ (Old) <blank> ○ (New) Oversharing a dashboard may result in minor confidentiality impacts in cases where a user shares a dashboard with a user, group, or role that should not access to the dashboard.
Implement the x-frame-options: SAMEORIGIN security header	• Description ○ (Old) <blank> ○ (New) The following property controls the implementation of the security header X-Frame-Options: SAMEORIGIN. If

Documentation	Updates
	security attribute, or roles list, or otherwise does not have any configured (an "empty ACL"). As of the Xanadu release, an empty ACL will completely deny access. On versions prior to Xanadu, empty an ACL will allow unconditional access. When the glide.security.empty_acl.popup_window.enabled property is set to a secure value of "true", attempts to create, update, or save an invalid or empty ACL will be blocked, and a clientside model will be provided to configure a role or security attribute for the ACL. If the property is insecurely set to any other value, then such attempts will be allowed and no client-side model will be displayed. Note: This property is case sensitive. A value of "True" (capital "T") will be equivalent to "false". Additionally, this property will only function when the High Security (com.glide.high_security) plugin is installed and active. • Security Risk ○ (Old) <blank> ○ (New) Misconfigured or empty Access Control Lists (ACLs) can unintentionally grant unrestricted access to sensitive data and system functionality. When ACLs lack proper conditions, roles, or security attributes, they fail to enforce authorization boundaries, enabling attackers or unauthorized users to bypass security controls. This can lead to data breaches, privilege escalation, and compromise of confidentiality, integrity, and availability across the platform. • Fallback Value ○ (Old) <blank> ○ (New) false
Require authorization for XML requests	• Description ○ (Old) <blank> ○ (New) If "glide.basicauth.required.xml" is not set to the recommended value of "true", then this will disable Basic Authentication

© 2026 ServiceNow, Inc. All rights reserved.

Documentation	Updates
	Unauthenticated users are allowed to access and potentially manipulate the Favorites of the shared "Guest" user, increasing the risk of unauthorized UI customization, data exposure, and user interface misuse.
Disable inbound emails for locked out users	• Description ○ (Old) <blank> ○ (New) This property controls inbound email actions for locked out users. If "glide.pop3.process_locked_out" is set to "True", there may be an information disclosure as inbound emails would be received by users with locked accounts. • Security Risk ○ (Old) <blank> ○ (New) Allows locked-out users to continue submitting inbound emails that may create records or trigger workflows, posing a security risk by enabling potentially unauthorized actions.
Enable scoped admin application ACLs	• Description ○ (Old) <blank> ○ (New) Determines whether an application administration apps can inherit global access control list (ACL) rules. Useful when there are no scoped admin application ACLs defined for the record scope. • Security Risk ○ (Old) <blank> ○ (New) If "glide.security.scoped_administration.honor_global_acl" is not set to the recommended value

Documentation	Updates
	of "true", then a low privilege user with permissions to the application could potentially access sensitive records.
Log session audit events	• Description ○ (Old) <blank> ○ (New) When the Glide Property 'glide.authenticate.session_access.log_audit_event' is set to 'true', session audit events will be created in the sys_session_access_audit table. Information logged will include user, session ID (non-sensitive), IP address, roles, and policies. • Security Risk ○ (Old) <blank> ○ (New) Information about who accessed a session will not be logged to assist in incident investigations.
Minimize session activity timeout duration	• Description ○ (Old) <blank> ○ (New) This property determines the user session timeout. This determines how long a user session stays active. If "glide.ui.session_timeout" is not set to the recommended value of "60" minutes or less, then the session may stay valid for long even without activity. This could provide too large of a time window to enable session hijacking attacks. • Security Risk ○ (Old) <blank> ○ (New) A long session timeout allows inactive sessions to remain valid for extended periods, increasing the chance that an attacker could hijack the session before it expires.

Documentation	Updates
	• (Old) Configure the glide.active.session.timeout.exception.roles property to roles which should be exempt from active session timeouts. This property value is a comma separated list of roles. The default value is edge_encryption,mid_server,maint. • (New) Configure the glide.active.session.timeout.exception.roles property to roles which must be exempt from active session timeouts. This property value is a comma separated list of roles. The default value is edge_encryption,mid_server,maint.
Limit integrations' active session life span	• Technical Configuration Name ○ (Old) glide.integrations.active.session.life_span ○ (New) glide.integrations.active.session.life_span • Description ○ (Old) <blank> ○ (New) This configuration will enforce max lifespan on active guest HTTP sessions irrespective of inactive timeout. The configured value is in minutes and the value of zero will disable timing out the active sessions. This particular property is limited to integrations that have low-privilege access to an instance. • Security Risk ○ (Old) <blank> ○ (New) A larger maximum lifespan could allow an attacker to persist in a stolen session for longer, increasing the scope of a security incident. • Out of Box Value

Documentation	Updates
	○ (Old) <blank> ○ (New) 0 • Fallback Value ○ (Old) <blank> ○ (New) 0 Rule Script (New) Script updated to improve detection accuracy.
Limit guest's active session life span	• Description ○ (Old) <blank> ○ (New) This configuration will enforce max lifespan on active guest HTTP sessions irrespective of inactive timeout. The configured value is in minutes and the value of zero will disable timing out the active sessions. This particular property is limited to Guest users, which have low privilege access to an instance. • Security Risk ○ (Old) <blank> ○ (New) A larger maximum lifespan could allow an attacker to persist a stolen session for longer, increasing the scope of a security incident. • Out of Box Value ○ (Old) <blank> ○ (New) 0 Rule Script (New) Script updated to improve detection accuracy.
Enable CAPTCHA for customer registration	Description

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	• (Old) The property "sn_customerservice.captchaEnabled" determines if CAPTCHA validation is enabled or disabled for customer registration on the Customer Service Management Portal. • (New) The property "sn_customerservice.captchaEnabled" determines if CAPTCHA validation is enabled or disabled for customer registration on the Customer Service Management Portal.
Limit Allowed Number of Failed Login Attempts Before Lockout	• Description ○ (Old) <blank> ○ (New) The "SNC User Lockout Check" or "SNC User Lockout Check with Auto Unlock" script actions enable the administrator to manage the number of failed login attempts for a user. Two script actions are available that enable a site administrator to manage the number of times a user can provide correct password before getting locked out from the Now Platform. Additionally, the "glide.user.max_unlock_attempts" property controls the number of allowed failed login attempts. If the value of "glide.user.max_unlock_attempts" is increased above the recommended value of "5", it will increase the number of login attempts an attacker could make against a given user. • Security Risk ○ (Old) <blank> ○ (New) Allowing more attempts gives attackers additional opportunities to guess passwords, increasing the likelihood of unauthorized access and credential

Documentation	Updates
	compromise. Proper lockout configuration is critical to maintaining strong authentication security.
Enforce relative links	• Description ○ (Old) <blank> ○ (New) The "glide.cms.catalog_uri_relative" property enforces relative links from the URI parameter on /ess/catalog.do. If "glide.cms.catalog_uri_relative" is not set to the recommended value of "true", then the URL will not be sanitized with the enforceRelativeURL(url) function. This property impacts the legacy Content Management System (CMS) which has been replaced with Service Portal. • Security Risk ○ (Old) <blank> ○ (New) Absolute URLs can pose a security risk when used as a part of parameter or a field value, thus redirecting the source page to an adversary-controlled website.
Minimize Concurrent Interactive Sessions with Limit Concurrent Sessions Plugin	• Short Description ○ (Old) Minimize Concurrent Interactive Session Quantity When Limit Concurrent Sessions Plugin Is Installed ○ (New) Minimize Concurrent Interactive Sessions with Limit Concurrent Sessions Plugin • Description ○ (Old) <blank> ○ (New) The property "glide.authenticate.max.concurrent.interactive.sessions" controls the number of active sessions that can be open for a user when the Limit Concurrent Sessions (com.glide.limit.concurrent.sessions) plugin is enabled. It is recommended that

Documentation	Updates
	this value be the default of "1" to reduce the number of sessions that can be left open for a user. • Security Risk ○ (Old) <blank> ○ (New) A greater number of open sessions means there are more sessions that can potentially be hijacked.
Require authorization for SCHEMA requests	• Description ○ (Old) <blank> ○ (New) If "glide.basicauth.required.schema" is not set to the recommended value of "true", then basic authorization is not required for all Inbound Table Schema Processor requests. The Inbound Table Schema Processor handles incoming schema requests for the platform. • Security Risk ○ (Old) <blank> ○ (New) Omitting authentication from this processor will lead to unauthenticated access to instance schema data.
Block Expired Anti-CSRF Tokens	• Description ○ (Old) <blank> ○ (New) This property allows usage of an expired secure token to identify and validate incoming requests. This token is used to prevent cross-site request forgery attacks. • Security Risk ○ (Old) <blank> ○ (New) Allowing the use of previous or expired CSRF tokens exposes the application to replay attacks, enabling attackers

Documentation	Updates
	to reuse valid requests and potentially perform unauthorized actions on behalf of legitimate users. • Data Type ○ (Old) <blank> ○ (New) Boolean • Out of Box Value ○ (Old) <blank> ○ (New) false
Set automatic token cleanup for token credentials	• Description ○ (Old) <blank> ○ (New) If the property 'com.snc.platform.security.token.auth.cleanup' is set to the insecure value of 'false', expired API keys and HMAC secrets will not be deleted. This creates a potential for token reuse. If the token was expired due to leakage or compromise, reuse exposes the instance to anyone possessing the leaked token. Expired tokens are kept for the number of days defined by 'com.snc.platform.security.token.auth.days.expired.hmac_s and 'com.snc.platform.security.token.auth.days.expired.api_key. Integers value of 0 and greater are valid values. A value of 0 would cause the expired tokens to be deleted in the same day. The default of 7 days, or fewer, is recommended. • Remediation ○ (Old) Ensure the property 'com.snc.platform.security.token.auth.cleanup' does not exist in the sys_properties table or is set to 'true'. Ensure the properties 'com.snc.platform.security.token.auth.days.expired.api_key. and 'com.snc.platform.security.token.auth.days.expired.hmac_s do not exist in the sys_properties table or are set to 7 or less, where 7 corresponds to the number of days.

Documentation	Updates
	○ (New) Ensure the property 'com.snc.platform.security.token.auth.cleanup' does not exist in the sys_properties table or is set to 'true'. Ensure the properties 'com.snc.platform.security.token.auth.days.expired.api_key. and 'com.snc.platform.security.token.auth.days.expired.hmac_s do not exist in the sys_properties table or are set to 7 or less, where 7 corresponds to the number of days. • Security Risk ○ (Old) <blank> ○ (New) A high number of days increases the exposure period for token reuse.
Enable HTML sanitizer within Virtual Agent	• Description ○ (Old) <blank> ○ (New) This property controls the whether the HtmlSanitizerService is enabled. If "com.glide.cs.html.sanitizer.enabled" is not set to "true", then a Stored Cross-Site Scripting (XSS) attack is possible in the VA web client. • Security Risk ○ (Old) <blank> ○ (New) An XSS vulnerability can facilitate privilege escalation to higher-level roles, such as administrator, enabling broader lateral movement within the system.
Enable HTTP response headers configuration	Description • (Old) Reduce the risk of cookie/ session-related hijacking of web apps using a system property. If glide.http.headers_config.enabled isn't set to true, then response header configurations defined in the HTTP

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	Response Headers [sys_response_header] table aren't used. Security related HTTP response headers include Content Security Policy, which aids in XSS-related protections. For details on HTTP response headers, see HTTP Response Headers (https://www.servicenow.com/docs/csh?topicname=http-response-header.html&version=latest). • (New) Reduce the risk of cookie/session-related hijacking of web apps using a system property. If glide.http.headers_config.enabled isn't set to true, then response header configurations defined in the HTTP Response Headers [sys_response_header] table aren't used. Security related HTTP response headers include Content Security Policy, which aids in XSS-related protections. For details on HTTP response headers, see HTTP Response Headers (https://www.servicenow.com/docs/csh?topicname=http-response-header.html&version=latest).
Prevent users from accepting warning to bypass CSRF validation	• Description ○ (Old) <blank> ○ (New) This property prevents users from being able to accept a warning which allows a potentially malicious request to be sent to the instance. This warning appears when a POST request fails due to having a mis-matched anti-CSRF token belonging to one of the victim's other active sessions. If "glide.security.csrf.strict.validation.mode" is not set to the recommended value of "true", then an attacker can formulate a CSRF attack utilizing a leaked anti-CSRF token from a different active session belonging to the victim. A POST request to an instance contains an anti-CSRF token within "sysparm_ck" or "XUserToken" which matches the user's current session. If the anti-CSRF token is instead tied to one of the user's other active sessions, the POST request will return a 302 redirection to security_interceptor.do with a "Continue" button available to the user when this property is set to "false".

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	Clicking this button will re-submit the request to the instance, except it will now having a valid anti-CSRF token. When this property is set to "true", the 302 redirection to the security_interceptor.do page will not display a "Continue" button and the user will not be allowed to resubmit the request. • Security Risk ○ (Old) <blank> ○ (New) A successful CSRF attack will allow an attacker to effectively perform any operation that the victim is able to perform.
Block access for delegated developers	• Description ○ (Old) <blank> ○ (New) This property determines whether a delegated developer can give assign roles to users through scripts. If "com.glide.sys.security.delegateddev.block_grant_roles" is not set to the recommended value of "true", then a delegated developer could assign roles to any user. This could lead to unapproved privilege escalation. • Security Risk ○ (Old) <blank> ○ (New) Delegated developers may assign roles to any user via scripts, posing a significant security risk of unauthorized privilege escalation.
Require Authorization for XSD Requests	• Description ○ (Old) <blank> ○ (New) The glide property "glide.basicauth.required.xsd" controls whether authentication is required in order to make a XSD request to an instance. If "glide.basicauth.required.xsd"

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	is not set to the recommended value of "true", then authentication is disabled for XSD requests on the instance. • Security Risk ○ (Old) <blank> ○ (New) This property allows unauthenticated access to XSD processor leaking sensitive information.
Turn off verbose SQL error messages for import processor	• Description ○ (Old) <blank> ○ (New) If this property is false a verbose SQL error message is returned, potentially causing sensitive information disclosure. • Security Risk ○ (Old) <blank> ○ (New) If verbose SQL error messages are returned, sensitive information such as database structure, table names, or query details may be exposed. This information can be leveraged by attackers to craft targeted SQL injection attacks or exploit other vulnerabilities, increasing the risk of data breaches and system compromise. Limiting error detail is essential to prevent information disclosure that aids malicious activity.
Escape scripts in scratchpad	• Description ○ (Old) <blank> ○ (New) The scratchpad is an easy way to set information on the server that can be accessed in the browser. An admin can script anything to be on it, including arbitrary data from arbitrary records. • Security Risk ○ (Old) <blank> ○ (New)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	If "glide.ui.escape_scratchpad" is not set to the recommended value of "true", then it is possible to execute malicious script like a cross-site scripting vulnerability.
Require authorization for PDF requests	• Description ○ (Old) <blank> ○ (New) If "glide.basicauth.required.pdf" is not set to the recommended value of "true", then this will disable Basic Authentication for PDF format export processor. This also happens when combined with a wrong role within the guest_user related property (For example a high privileged user such as Admin). This will lead to unauthenticated access to instance data. • Security Risk ○ (Old) <blank> ○ (New) Unauthenticated access to PDF export data, when combined with misconfigured guest user role, poses a significant risk of unauthorized data exposure.
Enable SNC access control plugin	Remediation • (Old) Ensure the plugin "com.snc.snc_access_control" is activated. Read the documentation on activating at https://www.servicenow.com/docs/csh?topicname=t_ActivateSNCAccessControl.html&version=lates • (New) Ensure the plugin "com.snc.snc_access_control" is activated.
Limit concurrent sessions across all nodes	• Description ○ (Old) <blank> ○ (New) This property is meant to be used with the "Limit Concurrent Sessions" plugin. When

Documentation	Updates
	this plugin is installed and configured, the number of open sessions can be limited per user. When this property is set, the number of sessions will be tracked across all nodes instead of a single application nodes. • Security Risk ○ (Old) <blank> ○ (New) If this property is not set to true, multiple sessions can be open across multiple nodes, increasing the likelihood of a successful session hijacking. • Plugin Applicability ○ (Old) <blank> ○ (New) com.glide.limit.concurrent.sessions
Enable security jump start plugin (ACL Rules)	• Description ○ (Old) <blank> ○ (New) Creates several important ACLs that validate the Access Controls on some of the key system tables within the Now Platform. These rules provide a jump-start on securing many system tables, making it easier for an organization to get an instance into production. The Security Jump Start (ACL Rules) plugin is installed automatically on all new instances. • Security Risk ○ (Old) <blank> ○ (New) Gaps in access control can allow unauthorized users to view, modify, or delete sensitive data, undermining data integrity, confidentiality, and compliance with organizational security policies.
Ensure archive table ACLs are checked	• Description ○ (Old) <blank> ○ (New)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	The 'glide.security.enable_archive_table_acls' controls if ACLs added to archive tables are evaluated (true) or if only the ACLs of the original table (i.e. the table the archive table was created from) are evaluated (false). There is no reason for this property to not be true since the original table ACLs will be evaluated regardless of its value and since a customer can simply avoid additional ACLs for an archive table by not adding them. • Security Risk ○ (Old) <blank> ○ (New) If the property is set to false, ACLs added to archived tables will be ignored, an action which is counterintuitive and may lead to authorization bypass.
Disable Entity Expansion within the XMLDocument2 Streaming Parser	• Description ○ (Old) <blank> ○ (New) If "glide.stax.allow_entity_resolution" is not set to the recommended value of "false", then this property allow XML entities to be expanded during parsing by the streaming parser (XMLDocument2). • Security Risk ○ (Old) <blank> ○ (New) XML entity expansion can lead to attacks such as ability to read system files, and Denial of Service. • Data Type ○ (Old) <blank> ○ (New) Boolean • Out of Box Value

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	○ (Old) <blank> ○ (New) false
Restrict flow context read access	• Description ○ (Old) <blank> ○ (New) When the Glide Property 'com.snc.process_flow.reporting.require_flow_access' is set to a value of true, there is an additional access check for a user trying to read a flow context. A user must have access to the parent flow to be able to read the flow context. • Security Risk ○ (Old) <blank> ○ (New) There may be minor information disclosure if this property is not set securely.
Restrict downloadable MIME types	• Description ○ (Old) <blank> ○ (New) If the property "glide.ui.attachment.force_download_all_mime_types" is set to true, then the "glide.ui.attachment.download_mime_types" property will be overridden so that all MIME types will be downloaded rather than rendered by the browser. For example, downloading text/html forces an HTML file to be downloaded to the client as a file rather than viewed inline in the browser, preventing a XSS attack. • Security Risk ○ (Old) <blank> ○ (New)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	XSS can lead to easily attained privilege escalation to higher roles such as admin where more lateral movement can be taken.
Minimize entity expansion threshold for GlideXMLUtil scriptable	• Description ○ (Old) <blank> ○ (New) This property controls the maximum amount of entity expansion within an XML Parser. If "glide.xmlutil.max_entity_expansion" is not set to the recommended value of 3000 or less, then the GlideXMLUtil parsing scriptable may be vulnerable to denial of service attacks. • Security Risk ○ (Old) <blank> ○ (New) A Denial-of-Service (DoS) vulnerability poses a security risk by allowing attackers to overwhelm or crash a system, rendering it unavailable to legitimate users and potentially disrupting critical operations.
Restrict Global App Development by Role	• Short Description ○ (Old) Restrict Global App Development by Role ○ (New) Restrict Global App Development by Role • Description ○ (Old) <blank> ○ (New) The property "sn_g_app_creator.allow_global" controls which users can create applications in the global scope using the Guided Application Creator. If "sn_g_app_creator.allow_global" is set to the recommended value of "false," users need the role "sn_g_app_creator.global" to create an application in the global

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	scope using Guided Application Creator. If "sn_g_app_creator.allow_global" is set to the insecure value of "true" then all users with only the base role "sn_g_app_creator.app_creator" can create an application in the global scope using Guided Application Creator. Applications in the global scope do not contain scope protections allowing a developer to access greater features and functions beyond a specific scope. • Security Risk ○ (Old) <blank> ○ (New) Limiting global application development to users with the additional role follows the principle of least privilege.
Enable ACLs to Control Live Profile Details	• Description ○ (Old) <blank> ○ (New) Use the glide.live_profile.details property to designate whether a user should be able to view all detail fields, such as company name and phone numbers, in a live profile under the live feed feature. If "glide.live_profile.details" is set to the value of "Hide", then no live profile information is visible to user. If it is set to show, all information is visible. When glide.live_profile.details" is set to the value of "ACL", information is visible based on the user's profile ACLs. • Security Risk ○ (Old) <blank> ○ (New) Exposing sensitive user information such as company affiliation and contact details to unauthorized users increases the risk of data leakage and violating privacy controls if ACLs are not enforced.
Set safe content security policy for SVG files	• Description ○ (Old) <blank> ○ (New)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	This property adds "script-src none" to the ContentSecurity-Policy header when SVGs are accessed via the ".iix" file extension, which prevents the exploitation of stored XSS from crafted file attachments stored within the instance. • Security Risk ○ (Old) <blank> ○ (New) Without this policy, a malicious actor could trick a user into running arbitrary JavaScript code in their web browser leading to consequences such as data exfiltration or session takeover.
Enable Jelly JS interpolation protection	• Description ○ (Old) <blank> ○ (New) This property allows a customer to turn on or off interpolation protection. Interpolation protection ensures that when Jelly expressions are used in JavaScript, they must be deemed safe by either falling under certain categories OR being marked as SAFE in the expression itself. Without this mitigation enabled, a malicious actor can send a crafted GET parameter to a Jelly page and cause the contents of that parameter to be evaluated as server-side JavaScript with admin privileges. • Security Risk ○ (Old) <blank> ○ (New) If "glide.ui.jelly.js_interpolation.protect" is not set to the recommended value of "true", then dangerous jelly expressions interpolated in JavaScript are allowed and user can execute code using jelly template.
Require AJAXGlideRecord ACL checking	• Description ○ (Old) <blank> ○ (New)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	This property toggles ACL validation for GlideAjax API calls. If "glide.script.secure.ajaxgliderecord" is not set to the recommended value of "true", then ACL validation will not be completed for GlideAjax requests. • Security Risk ○ (Old) <blank> ○ (New) This could lead to server-side resources being accessed by users without proper authorization.
Enforce OCSP check on network error	• Description ○ (Old) <blank> ○ (New) If the glide property "com.glide.communications.httpclient.ocsp_allow_network_ is not explicitly set to the recommended value of false, and the OCSP (Online Certificate Status Protocol) check encounters a network-related issue—such as a timeout or failure to retrieve revocation data —the system will treat the OCSP validation as successful by default. • Security Risk ○ (Old) <blank> ○ (New) An attacker using a revoked certificate could exploit this by simply omitting the OCSP response during a connection attempt. In such cases, the client would incorrectly accept the revoked certificate as valid, thereby undermining the integrity of the Public Key Infrastructure (PKI) and the trust model that underpins secure web communications. The use of revoked certificates is often indicative of malicious activity, unless attributable to temporary synchronization issues between certificate authorities and OCSP responders.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
Require authorization for excel requests	• Description ○ (Old) <blank> ○ (New) If "glide.basicauth.required.excel" is not set to the recommended value of "true", then this will disable Basic Authentication for EXCEL format export processor. This also happens when combined with a wrong role within the guest_user related property (For example a high privileged user such as Admin). • Security Risk ○ (Old) <blank> ○ (New) Unauthenticated access to Excel export data, when combined with misconfigured guest user role, poses a significant risk of unauthorized data exposure.
Use of secure insert multiple operation within import set API	• Description ○ (Old) <blank> ○ (New) This property controls whether GlideRecordSecure or GlideRecord is used for the Insert Multiple operation within Import Set API. If this property is set to "false", then GlideRecordSecure will be used to insert records and Table level ACLs will be evaluated. If this property is set to "true", then GlideRecord will be used to insert records and Table level ACLs will not be evaluated. • Security Risk ○ (Old) <blank> ○ (New) If this property is not set to the recommended value of "false", then a low privilege user may be able to insert data into tables outside the scope of their privileged roles.

Documentation	Updates
Minimize absolute session timeout duration	• Description ○ (Old) <blank> ○ (New) If "glide.ui.user_cookie.max_life_span_in_days" is not set to the recommended value of "30" or other appropriate value, then a very long life session could be more vulnerable to session hijack attacks. • Security Risk ○ (Old) <blank> ○ (New) A long session lifespan extends the window of opportunity for attackers to hijack active sessions, increasing the likelihood of unauthorized access if credentials or session tokens are compromised.
Disable locked form elements debugging	• Description ○ (Old) <blank> ○ (New) If "glide.security.explain.write.locks" is not set to the recommended value of "False", then additional debug information is displayed on locked form elements. • Security Risk ○ (Old) <blank> ○ (New) Displaying debug information on locked form elements could lead to information disclosure.
Deny unauthorized access to request items	• Description ○ (Old) <blank> ○ (New) This property defines a default behavior for the "retrieveAddress" API. When there are no roles given in property "glide.sc.req_for.roles", the Client Callable Script Include 'ScriptServiceCatalogGetLocation' can be

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	called by any unprivileged logged-in user and can retrieve the address of any other users in the system. • Security Risk ○ (Old) <blank> ○ (New) If "glide.sc.req_for.roles.default" is not set to the recommended value of "deny" (allow) and the value of glide.sc.req_for.roles is empty, then any user can request items for other users allowing unauthorized resource access.
Check UI action conditions before execution	• Description ○ (Old) <blank> ○ (New) If "glide.security.strict.actions" is not set to the recommended value of "true", then there will be no validation on the table UI before execution. Setting this property to secure value will add an extra layer of security validation. • Security Risk ○ (Old) <blank> ○ (New) Users may perform operations they may not be authorized for— potentially leading to unauthorized data manipulation, privilege escalation, and bypassing of access controls designed to protect sensitive records.
Sanitize All Translated HTML Fields	• Description ○ (Old) <blank> ○ (New) When the Glide Property 'glide.translated_html.sanitize_all_fields' is set to the value 'true', all translated_html elements will be sanitized using an HTML sanitizer. When the property is set to 'false', an element will only be sanitized if a dictionary attribute, html_sanitize, is set to true.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	• Security Risk ○ (Old) <blank> ○ (New) Sanitizing HTML elements is best practice to ensure an attacker cannot embed malicious content that may lead to Cross Site Scripting (XSS) attacks.
Require write access to access service catalog add item page	• Description ○ (Old) <blank> ○ (New) When the Glide Property 'glide.sc.request.add_item_write_access' is not set to 'true', any logged in user can access the Add Catalog Item UI page. This could result in unauthorized operations performed on catalog items. • Security Risk ○ (Old) <blank> ○ (New) This creates a risk of unauthorized modifications or additions to catalog items, potentially leading to service disruption, fraudulent requests, or exposure of sensitive data. Misconfigured access controls in catalog management can undermine system integrity.
Restrict knowledge bases access	• Description ○ (Old) <blank> ○ (New) This property is being used in the functionality of knowledge record user criteria security. If "glide.knowman.block_access_with_no_user_criteria" is not set to the recommended value of "true", then knowledge bases without can read or can contribute user criteria become readable and writable by all users. • Security Risk ○ (Old) <blank> ○ (New)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	Knowledge bases lacking explicit "can read" or "can contribute" user criteria may become accessible and editable by all users, potentially leading to unauthorized access and modification of sensitive knowledge content.
Activate role based multi-factor authentication	• Description ○ (Old) <blank> ○ (New) This property enforces multi-factor authentication based on the roles assigned to the user. If this property is set to true, then it will enforce role-based multi-factor authentication for all users described in the multi_factor_criteria table. This table enforces multi-factor authentication based on the roles assigned to the user. If a user has been assigned "admin", "security_admin" or "user_admin" roles in the multi-factor roles list, MFA will be enforced. • Security Risk ○ (Old) <blank> ○ (New) Enforcing MFA based on roles strengthens authentication security and aligns with best practices for protecting privileged accounts.
Verify certificate chain and hostname	• Description ○ (Old) <blank> ○ (New) When the Glide Property "com.glide.communications.httpclient.verify_hostname" is not set to the secure value of "true", the hostname and certificate chain presented by remote hosts during a TLS connection initiated from the ServiceNow instance are not validated. • Security Risk ○ (Old) <blank> ○ (New)

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	This could compromise the security of the TLS connection and allow person-in-the-middle attacks, where communications between two parties are intercepted. This may lead to sensitive data disclosure.
Restrict uploaded MIME types	• Description ○ (Old) <blank> ○ (New) This property is used to activate MIME type checking for uploads. • Security Risk ○ (Old) <blank> ○ (New) If "glide.security.file.mime_type.validation" is not set to the recommended value of true, then MIME type validation for file attachments will not take place which could allow malicious file types to be uploaded.
Disable soap fault stack trace display	• Description ○ (Old) <blank> ○ (New) If "glide.soapfault.display_stack_trace" is not set to the recommended value of "False", then a stack trace in a SOAP fault detail element is displayed. • Security Risk ○ (Old) <blank> ○ (New) Displaying stack traces to users could lead to sensitive information disclosure.
Validate SOAP content type	• Description ○ (Old) <blank> ○ (New) If "glide.soap.require_content_type_xml" is not set to the recommended value of "true", then there is no validation for the SOAP request.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	• Security Risk ○ (Old) <blank> ○ (New) This lack of validation can enable Cross-Site Request Forgery (CSRF) attacks, allowing malicious actors to trick authenticated users into sending unauthorized SOAP requests.
Enable ACLs for Encoded Query in Simple List Widget	• Description ○ (Old) <blank> ○ (New) When the Glide Property "glide.service_portal.enable_acls_for_encoded_query_in_li is not set to "true", a user may be able to bypass ACLs evaluation on a query condition in Simple List Widget. • Security Risk ○ (Old) <blank> ○ (New) It is best practice to evaluate ACLs within queries to ensure a user has access to the fields being queried to prevent unauthorized data leakage.
Restrict Impersonation to Admin	• Description ○ (Old) <blank> ○ (New) When the Glide Property glide.sys.permissive.impersonate is set to a value of false , only users with the admin role may impersonate. When this value is set to true , users may be able to make use of application components that expose impersonation APIs to impersonate a higher privileged user. • Remediation ○ (Old) Ensure the Glide Property glide.sys.permissive.impersonate is set to a value of false . If this property does not exist, the default value is false . This value

Documentation	Updates
	is safe-overridable. If the property is set to false , it cannot be changed going forward. ○ (New) Ensure the Glide Property glide.sys.permissive.impersonate is set to a value of false . If this property does not exist, the default value is false . This value is safe-overridable. If the property is set to false , it cannot be changed going forward. • Security Risk ○ (Old) <blank> ○ (New) May result in unauthorized resource access if these application components are misconfigured.
Require authorization for WSDL request	• Description ○ (Old) <blank> ○ (New) If "glide.basicauth.required.wsdl" is not set to the recommended value of "true", then this will disable Basic Authentication for WSDL requests. WSDL is a protocol that is used to describe web services such as instance table schemas, and is not a mechanism for sharing the data within tables. Setting this property to "true" allows for disclosure of table schemas to unauthenticated users. • Security Risk ○ (Old) <blank> ○ (New) Unauthenticated access to WSDL Requests, when combined with misconfigured guest user role, poses a risk of unauthorized table schema exposure.
Restrict HR case updates from personal emails	• Description ○ (Old) <blank> ○ (New) When the Glide Property 'sn_hr_core.restrict_guest_email' is not

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	set to 'true', a user can send an email from a personal account referencing the HR case to be included in the worknotes. This could result in minor confidentiality or integrity issues if the personal email is compromised or communicating insecurely. An admin may want to restrict the ability of users to respond to HR cases via their personal email, since they cannot be confident of the user accessing the personal email account. • Security Risk ○ (Old) <blank> ○ (New) This creates a risk of minor confidentiality and integrity issues because personal email accounts may be insecure or compromised, and administrators cannot verify the identity or security posture of those accounts. Allowing this behavior weakens control over sensitive HR communications and increases exposure to data leakage.
Anti-CSRF token validation time	• Description ○ (Old) <blank> ○ (New) Time in seconds for a secure token to expire. When the user session expires, the secure token expires with it, unless the "allowing reuse of expired tokens are allowed" property is enabled, and its within the time frame described by this property. This token is used to prevent cross site request forgery attacks. (default is 86400 seconds or 1 day) • Security Risk ○ (Old) <blank> ○ (New) The time limit for a CSRF token to expire defines how long the token remains valid for verifying legitimate user requests; if set too long, it increases the risk that an attacker could reuse a stolen token to

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	perform unauthorized actions, while a shorter expiration window reduces this risk by narrowing the attack window.
Require authorization for SOAP requests	• Description ○ (Old) <blank> ○ (New) The glide property 'glide.basicauth.required.soap' controls whether basic authentication is required to make a SOAP request to an instance. If 'glide.basicauth.required.soap' is not set to the recommended value of 'true', then unauthenticated users performing SOAP operations will be mapped to the soap.guest user. This may enable an unauthenticated user to perform operations on the instance as if a logged in user to the instance. There may be additional impact if the user define within 'com.glide.soap.guest_user' is assigned additional roles. • Security Risk ○ (Old) <blank> ○ (New) Unauthenticated access to SOAP export data, when combined with misconfigured guest user role, poses a significant risk of unauthorized data exposure.
	• Description ○ (Old) <blank> ○ (New) When the Glide Property 'glide.knowman.show_user_feedback' is not set to 'never', feedback comments will be visible on knowledge articles to users with the roles defined in the Glide Property 'glide.knowman.show_user_feedback.roles'. Due to the potentially sensitive information in a feedback comment, an instance admin may not want the feedback to be visible. • Security Risk

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	○ (Old) <blank> ○ (New) If this property is not set to 'never', there could be confidentiality impacts if sensitive information is disclosed in feedback.
Enforce strict user image upload	• Description ○ (Old) <blank> ○ (New) If "glide.security.strict.user_image_upload" is not set to the recommended value of "true", then ACLs are not enforced on image uploads to the Photo field. When the property is set to true, the table ACLs are enforced when uploading photos, only allowing authorized users to upload an image. • Security Risk ○ (Old) <blank> ○ (New) An unauthorized user may upload an image to another user's profile.
Minimize session window timeout duration	• Description ○ (Old) <blank> ○ (New) This property affects the expiry of the cookie. After each successful authentication, the cookie will expire after the number of days specified as the property value. If "glide.ui.user_cookie.life_span_in_days" is not set to the recommended value of 15 or less, then there is a higher risk that the cookie, if stolen, can be used for longer. • Security Risk ○ (Old) <blank> ○ (New) A longer life span increases the time window that a stolen cookie will be used.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
Require authorization for API requests	• Description ○ (Old) <blank> ○ (New) If "glide.basicauth.required.api" is not set to the recommended value of "true", then this will disable Basic Authentication on API request and will lead to unauthenticated access to instance data. • Security Risk ○ (Old) <blank> ○ (New) Unauthenticated access to API data, when combined with misconfigured guest user role, poses a significant risk of unauthorized data exposure.
Disable external content URL	• Description ○ (Old) <blank> ○ (New) If "glide.ui.url.external.content" is not set to the recommended value of "false", then Connect chat will retrieve external link metadata in order to render richer content in messages with links to Youtube, news articles, images, etc. • Security Risk ○ (Old) <blank> ○ (New) This could lead to Server Side Request Forgery (SSRF) attacks.
Enforce strict elevate privilege	• Description ○ (Old) <blank> ○ (New) When this property is set to 'true', roles marked as "privileged" must always be manually elevated by an admin user upon new session creation in order for the user to be granted the role's capabilities. When 'false', roles marked as "privileged" are automatically elevated upon an admin

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	user new session, and do not need to be manually elevated (with exception of "security_admin"). Setting this property to secure value will add an extra layer of security validation to role elevation by privileged user. • Security Risk ○ (Old) <blank> ○ (New) This risks potential privilege misuse or accidental execution of highimpact actions. Requiring manual elevation adds a deliberate security checkpoint that helps prevent unauthorized or unintended access to sensitive capabilities.
Disable Multi-SSO debugging	• Description ○ (Old) <blank> ○ (New) This property controls debug logging for multiSSO. • Security Risk ○ (Old) <blank> ○ (New) MultiSSO debugging features could lead to unintended sensitive information leak.
Enforce strict security of session cookies	• Description ○ (Old) <blank> ○ (New) If "glide.ui.secure_cookies" is not set to the recommended value of "true", then additional cookie security and strict cookie validation is not performed. • Security Risk ○ (Old) <blank> ○ (New) This could allow an attacker to bypass cookie validation leading to unauthorized resource access.

Documentation	Updates
Enable the hardened java security manager	• Description ○ (Old) <blank> ○ (New) This property contains Java classname of current Java security manager. ServiceNow has standardized on the Contextual Security Manager. If "glide.security.manager" is not set to the recommended value of "com.glide.sys.security.ContextualSecurityManager", then the instance may be using an obsolete Java security manager which is missing expected hardening policies. • Security Risk ○ (Old) <blank> ○ (New) Without this hardening, it may be possible for a malicious actor with script execution access to achieve remote code execution on the instance.
Restrict access to specific IP ranges plugin	• Description ○ (Old) <blank> ○ (New) This plugin when set to true restricts access to specific IP ranges. Unless public access is intended for the instance, administrators should limit access to their assigned IP net blocks. An exclusion list (Deny) or an inclusion list (Allow) of IP addresses can be created through IP Address Access Control (ip_access_list.do). • Security Risk ○ (Old) <blank> ○ (New) Allowing unrestricted public access to a ServiceNow instance without properly configuring the IP Address Access Control plugin exposes the system to unauthorized access and

Documentation	Updates
	potential exploitation from any IP address, undermining networklevel security and increasing the attack surface.
Require authorization for unload requests	• Description ○ (Old) <blank> ○ (New) This property performs authentication while retrieving data from tables/pages in the form of unload data on the instance. If "glide.basicauth.required.unl" is not set to the recommended value of "true", then this will disable Basic Authentication for the UNL format export processor. This also could be combined with a wrong role within the guest_user related property, this will lead to unauthenticated access to instance data. • Security Risk ○ (Old) <blank> ○ (New) This property may allow unauthenticated access to unload data exports—especially when combined with misconfigured guest user roles—creating a serious risk of unauthorized exposure of instance configuration and data.
Require authorization for import requests	• Description ○ (Old) <blank> ○ (New) This property performs this authentication while importing data sources into the instance tables/pages. It restricts any guest users who are currently accessing this data. If "glide.basicauth.required.importprocessor" is not set to the recommended value of "true", then unauthenticated users could access import processor. Additional access controls, ie ACLs, are still enforced, but this value allows a guest user import request to be processed and not summarily denied. • Security Risk

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	○ (Old) <blank> ○ (New) This property may allow unauthenticated users to initiate import requests via the import processor, potentially bypassing initial authentication checks and increasing the risk of unauthorized data manipulation despite enforced ACLs.
Require authorization for script requests	• Description ○ (Old) <blank> ○ (New) This property determines if basic auth is required to invoke a scripted processor. Any records accessed by the scripted processor will still use other access controls, ie ACLs, before returning any data. If "glide.basicauth.required.scriptedprocessor" is not set to the recommended value of "true", then an attacker could access sensitive information such as an unauthenticated (guest) user attempting to access an email through the EmailDisplay sys_processor. • Security Risk ○ (Old) <blank> ○ (New) This property may allow unauthenticated users to invoke scripted processors, potentially exposing sensitive information despite existing ACLs.
Enable contextual security plugin	• Description ○ (Old) <blank> ○ (New) The "Contextual Security: Role Management" plugin helps manage user groups and roles to protect information through role-based access controls. The plugin efficiently consolidates duplicate entries for inherited roles, and secures a record/information using create, read, write, and delete functionality. After it is installed and activated, the

Documentation	Updates
	dictionary roles (created by simple security manager) are no longer tested. Instead, the Now Platform looks for ACL rules on fields and tables. It secures the data with the help of ACL rules instead of traditional, role-based dictionary rules implemented by simple security manager. Even if you configure the dictionary form and add roles to a dictionary entry, no change in rights occurs. • Security Risk ○ (Old) <blank> ○ (New) Failing to transition fully to ACL-based controls may leave sensitive data exposed due to overlooked or outdated dictionary role configurations.
Enforce password reset on API requests	• Description ○ (Old) <blank> ○ (New) When a user is marked for "Password needs reset" they must provide a new password at the next authentication attempt. This property controls whether the password reset is mandatory before making API calls. If "glide.authenticate.api.user.reset_password.mandatory" is not set to the recommended value of "true", then user accounts marked as "Password needs reset" can still perform most common operations by querying the table API through basic authentication. • Security Risk ○ (Old) <blank> ○ (New) This could allow information disclosure in the event that stale accounts are compromised.
Disable logger for low privilege users in script sandbox	• Description ○ (Old) <blank> ○ (New)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	If "glide.security.sandbox_no_logging" is set to "false", then logging will be available for low-privileged users using sandboxed scripts. This property controls Glide System's ability to log scripts being executed in the sandbox environment. • Security Risk ○ (Old) <blank> ○ (New) A low privileged user could inject logs allowing the malicious user to potentially obfuscate an attack.
Require authentication by default for client-callable script includes	• Description ○ (Old) <blank> ○ (New) This property makes sure that Client-Callable Script Includes, also known as Ajax Script Includes, are not automatically made available to nonauthenticated users. If "glide.script.ccsi.ispublic" is not set to the recommended value of "False", then it will allow Script Includes to be run as public scripts and allow unauthenticated users access to instance data. • Security Risk ○ (Old) <blank> ○ (New) Sensitive business logic or data is potentially exposed, increasing the risk of unauthorized access to instance resources.
Enforce field ACLs for inbound query requests	• Description ○ (Old) <blank> ○ (New) If the property "glide.export.query.enforce_field_acl" is set to "true", field ACLs will be checked against the incoming query, and reject the query if the user is unauthorized. If

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	the property is false, ACLs will NOT be checked against incoming query and will continue to execute. • Security Risk ○ (Old) <blank> ○ (New) This can result in information disclosure to unauthorized parties.
Limit UI active session life span	Functional Impact • (Old) Enforces max life-span on active authenticated HTTP sessions irrespective of inactive timeout. The configured value is in minutes. A value of zero will disable timing out the active sessions. The max life-span should be more than inactive timeout glide.ui.session_timeout (default 30 minutes). • (New) Enforces max life-span on active authenticated HTTP sessions irrespective of inactive timeout. The configured value is in minutes. A value of zero will disable timing out the active sessions. The max life-span must be more than inactive timeout glide.ui.session_timeout (default 30 minutes). Rule Script (New) Script updated to improve detection accuracy.
Restrict access to emails with empty target table	• Description ○ (Old) <blank> ○ (New) If "glide.email.email_with_no_target_visible_to_all" is not set to the recommended value of false, then low level users will have access to emails which are not their own. • Security Risk

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	○ (Old) <blank> ○ (New) Emails that lack a specific target record may become visible to all users, resulting in unauthorized access to potentially sensitive communication and violating principles of least privilege and data confidentiality.
Enable account recovery	• Description ○ (Old) <blank> ○ (New) This property controls the account recovery feature which binds the ability to bypass single sign-on to specifically designated administrators. If "glide.sso.acr.enabled" is not set to the recommended value of "true", then the local interactive log-ins (username or password based) will be remain enabled when single signon is enabled on the instance. • Security Risk ○ (Old) <blank> ○ (New) Eliminating local interactive log-ins reduces the potential for unauthorized access to the instance.
Require authorization for RSS requests	• Description ○ (Old) <blank> ○ (New) This property controls basic authorization for inbound RSS requests. If "glide.basicauth.required.rss" is not set to the recommended value of "true", then this will disable Basic Authentication for RSS format export processor. This also could be combined with a wrong role within the guest_user related property, this will lead to unauthenticated access to instance data. • Security Risk

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.

Documentation	Updates
	○ (Old) <blank> ○ (New) Unauthenticated access to RSS export data, when combined with misconfigured guest user role, poses a significant risk of unauthorized data exposure.
Require authorization for csv requests	• Description ○ (Old) <blank> ○ (New) If "glide.basicauth.required.csv" is not set to the recommended value of "true", then this will disable Basic Authentication for CSV format export processor. This also happens when combined with a wrong role within the guest_user related property (Ex: high privileged role). This will lead to unauthenticated access to instance data. • Security Risk ○ (Old) <blank> ○ (New) Unauthenticated access to CSV export data, when combined with misconfigured guest user role, poses a significant risk of unauthorized data exposure.
Control lockout time for invalid password reset attempts	• Description ○ (Old) <blank> ○ (New) The password_reset.request.max_attempt_window property defines the number of minutes a user must wait to reset or change their password after exceeding the maximum number of unsuccessful attempts that is set with the password_reset.request.max_attempt property. • Security Risk ○ (Old) <blank> ○ (New)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	A value too low increases the risk of successfully brute forcing a password as a greater number of password reset attempts can be made.
Maximize reset password SMS complexity	• Description ○ (Old) <blank> ○ (New) If "password_reset.sms.default_complexity" is not set to the recommended value of "6" or greater, then a weak SMS validation token is used. • Security Risk ○ (Old) <blank> ○ (New) This increases the possibility of token guessing which could lead to account takeover.
Minimize reset password max SMS per day	• Description ○ (Old) <blank> ○ (New) The property "password_reset.sms.max_per_day" denotes the maximum number of SMS codes sent for verification per day for a user. • Security Risk ○ (Old) <blank> ○ (New) If the value is too high, it will be easier for attackers to brute force the SMS code.
Require CAPTCHA for guest walk-up experience in customer service application	• Description ○ (Old) <blank> ○ (New) The captcha for the Guest Walk-up experience prevents unauthenticated guest users to create bookings by requiring users to complete a captcha

© 2026 ServiceNow, Inc. All rights reserved.

Documentation	Updates
	verification. If captcha is not enabled, this could lead to automated creation of spam appointments to overwhelm the system or fill up all available booking spots creating a Denial of Service attack. • Security Risk ○ (Old) <blank> ○ (New) This exposes the system to spam appointments and resource exhaustion attacks, potentially filling all available booking slots and causing a Denial of Service (DoS). Without CAPTCHA, the platform lacks a critical control to prevent automated abuse and maintain service availability.
Minimize reset password request success window duration	• Description ○ (Old) <blank> ○ (New) If "password_reset.request.success_window" is not set to the recommended value of "1440" or less, then it increases the opportunity of someone else abusing the password reset functionality to gain unauthorized access to a user account. • Security Risk ○ (Old) <blank> ○ (New) Limiting the success window reduces the opportunity for abuse and strengthens account recovery security.
Enable MID audit log	• Description ○ (Old) <blank> ○ (New) The MID Server command audit log tracks details such as the command name, command hash, name of credential used and execution status. When enabled, users with the agent_security_admin role can view these logs in the MID Server Command Audit Logs

Documentation	Updates
	• Dependencies and Prerequisites ○ (Old) <blank> ○ (New) This setting only applies to instances using an active Management, Instrumentation, and Discovery (MID) Server. A MID Server enables communication and movement of data between a ServiceNow instance and external applications, data sources, and services. Setting up a MID Server requires downloading the MID Server package on a Linux or Windows host, setting up the connection with the given ServiceNow instance and configuring additional settings. Information and references can be found at https://www.servicenow.com/docs/csh?topicname=mid-serverlanding.html&version=latest. After it has been set up, a MID Server appears as a record in the MID Servers [ecc_agent] table on connecting instance. • Data Type ○ (Old) <blank> ○ (New) Boolean • Out of Box Value ○ (Old) <blank> ○ (New) false Rule Script (New) Script updated to improve detection accuracy.
Enforce URL allowlist check	• Description ○ (Old) <blank> ○ (New) If "glide.security.url.whitelist.strict_check" is not set to the recommended value of "true" then all external URLs are allowed for redirection when "glide.security.url.whitelist" is empty. If "glide.security.url.whitelist" is not empty, then only external URLs in the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	whitelist are allowed. Thus either setting "glide.security.url.whitelist.strict_check" to true OR ensuring "glide.security.url.whitelist" is set to a non-empty value with the allowed external URLs leaves the instance in a secure state. • Security Risk ○ (Old) <blank> ○ (New) If all external URLs are allowed for redirection, this could allow an attacker to redirect a user to a malicious website.
Disable secure cookie debugging	• Description ○ (Old) <blank> ○ (New) If "glide.secure_cookie.debug" is not set to the default value of "false", then debug messages in the SecureUserCookie and Cookie class are logged in localhost log. • Security Risk ○ (Old) <blank> ○ (New) Logging debug messages from the SecureUserCookie and Cookie class could lead to sensitive information disclosure.
Maximum allowed attachment size	• Description ○ (Old) <blank> ○ (New) This property "com.glide.attachment.max_size" controls the maximum size of uploaded attachment. Note: a real attachment size is calculated through multiplication 10241024value of property "com.glide.attachment.max_size". If the value of property "com.glide.attachment.max_size" is 1024 then the max allowed attachment size is 1Gb.

Documentation	Updates
	• Security Risk ○ (Old) <blank> ○ (New) The platform can accept large files that could fill up storage or cause a denial of service.
Enable email spam scoring and filtering	• Description ○ (Old) <blank> ○ (New) The Email Filter (com.glide.email_filter) plugin installs email filtering within the instance. This filtering identifies existing headers, which enables the administrator to decide what to do with the email based on the associated header. This plugin adds a header to each message. The header can be used for filtering within the instance. This feature is very helpful for filtering out spam. Note: Please make sure prerequisite properties "glide.email.read.active" is set to true, as this control only applies when inbound email is enabled. • Security Risk ○ (Old) <blank> ○ (New) Enabling and configuring email filtering is essential for reducing exposure to spam and maintaining system integrity.
Disallow infected file download	• Description ○ (Old) <blank> ○ (New) When the property "com.glide.snap.infected_download_allowed" is set to "true", users can still download nonscanned attachments in the case that the antivirus service is down or unreachable. • Security Risk

Documentation	Updates
	○ (Old) <blank> ○ (New) A user may download a malicious file to their desktop.
Block rooted or jailbroken mobile devices	• Description ○ (Old) <blank> ○ (New) If "glide.sg.allow_rooted_jailbroken_device" is not set to the recommended value of "false", then the mobile app will allow users to use the app from jailbroken or rooted mobile devices. Jailbroken or rooted mobile devices run untrusted code at the system level that can bypass the platform's security model which our mobile apps rely on. Setting "allow_rooted_jailbroken_device" to "false" enables a limited client-side check to display an error message to the user if attempting to use the app from one of these devices. This configuration maps to MASVS v1.4.2 requirement 8.1 at R-level. • Security Risk ○ (Old) <blank> ○ (New) Allowing rooted or jailbroken mobile devices significantly increases the risk of credential theft, data leakage, and malicious code execution.
Invalidate Session After OAuth Token Expiration [New in Security Center 2.0]	• Description ○ (Old) <blank> ○ (New) When an OAuth access token is issued, the response includes a cookie. Users can use this cookie to continue using a session even after the OAuth token used to create that session expires. Use the glide.authenticate.oauth.post.token.expiration.cookie_auth. system property to prevent this. • Remediation

Documentation	Updates
	○ (Old) Ensure the Glide Property glide.authenticate.oauth.post.token.expiration.cookie_auth. is set to a value of true. When the record does not exist in the sys_properties table, the default is false. A record is created for newly provisioned instances. ○ (New) Ensure the glide.authenticate.oauth.post.token.expiration.cookie_auth. system property exists in the System Properties [sys_properties] table, and is set to a value of true. • Security Risk ○ (Old) <blank> ○ (New) If an OAuth token is leaked or compromised, the lack of expiration would allow an attacker to use and extend the session via the created cookie. Malicious users can use sessions to access unauthorized resources and take unauthorized actions. Set this property to the secure value to eliminate this hidden session extension mechanism and reduce replay risk by enforcing token expiration. • Functional Impact ○ (Old) <blank> ○ (New) Impact when set to true: Sessions end immediately when the access token expires. Cookies no longer refresh session validity. Clients must use refresh tokens or re-authenticate to obtain a new access token. Potential Breakage: Legacy clients or custom integrations relying on cookie-based session extension fail after token expiry. Long-running jobs without token renewal logic may encounter 401 errors. What Continues to Work: Standard OAuth flows with refresh tokens. Properly designed integrations that renew tokens proactively • CVSS Score

Documentation	Updates
	○ (Old) 5.4 ○ (New) 6.8 • Data Type ○ (Old) <blank> ○ (New) Boolean • Out of Box Value ○ (Old) <blank> ○ (New) true Rule Script (New) Script updated to improve detection accuracy.
Restrict XML external entities	• Description ○ (Old) <blank> ○ (New) Use the glide.xml.entity.whitelist.enabled and glide.xml.entity.whitelist system properties to prevent your instance from processing XML external entities from untrusted sources. XML external entity (XXE) attacks occur when a malicious actor modifies incoming XML to access data or interact with otherwise restricted systems. An attacker can use the Document Type Definition (DTD) to include arbitrary HTTP requests that the server may execute. This could lead to additional attacks using the server's trust relationship with other entities. To help prevent these attacks, the glide.xml.entity.whitelist.enabled system property limits the sources from which your instance executes XML. Use the glide.xml.entity.whitelist property to define a set of trusted sources. The value for "glide.xml.entity.whitelist" set to "http://java.sun.com/j2ee/dtds/" is a reference to the DTDs (Document

Documentation	Updates
Restrict unauthenticated access to attachments	• Description ○ (Old) Secure the images on your instance to prevent sensitive information leak. Images on your instance are accessible via urls that end in .iix. Set the glide.image_provider.security_enabled system property to true to prevent access to your images via these URLs. [Note] This property is not honored for images from the attachment table if the origin table is one of: Stationeries [sysevent_email_style] Welcome Page Sections [sys_home] System Properties [sys_properties] ○ (New) Use the glide.image_provider.security_enabled property restrict unauthenticated access to image attachments. If set to true, images are visible to any authenticated user but no unauthenticated user. If set to false, images are visible to anyone with a URL to the attachment. Thumbnails of an attached image maintain the same policy as the original attached image and are accessible to the same set of users as the original attached image. When this property is enabled, more fine grained access control for unauthenticated users is obtained through entries in the Security Allow/Deny List Entities [sys_security_restricted_list] table and through the declaration of public KB articles for those images attached to KB articles. These exceptions to the default policy for unauthenticated users when this property is true are applied in the following order. Note in these exceptions, "parent table" refers to the table of the original image attachment from which a thumbnail is generated. 1. If the table of an attached image or parent table of a thumbnail image is deny-listed in the Security Allow/Deny List Entities [sys_security_restricted_list] table, access is denied to the image/thumbnail. 2. If the table of an attached image or parent table of a thumbnail image is allow-listed in the Security Allow/Deny List Entities [sys_security_restricted_list] table, access

	can no longer be able to access image attachments unless explicitly allowed using one of the exclusion procedures.
Enable a deny-list password validation check	• Technical Configuration Name ○ (Old) glide.enable.blacklist_password ○ (New) glide.enable.blacklist_password, blacklisted_password • Description ○ (Old) <blank> ○ (New) Use the glide.enable.blacklist_password property to monitor deny-list passwords. When the property is set to true, the user's password is checked against a specific list of deny-listed passwords. This denial prevents users from using a password from a set of breached passwords. You can maintain the list by inserting passwords into the Excluded Password [blacklisted_password] table. ServiceNow provides a small, medium, or large password list that can be inserted to the Excluded Password table through the UI page found at All > Password Policy > Exclusion List Management. ServiceNow installs the small list of 5,000 passwords to new instances. • Remediation ○ (Old) Ensure the property "glide.enable.blacklist_password" is set to "true". ○ (New) Ensure that the glide.enable.blacklist_password system property is set to true and that the Excluded Password [blacklisted_password] table contains a minimum of 5,000 records. • Security Risk

Documentation	Updates
	can use to make inbound/outbound connections to an instance. The exact IP ranges removed from the IP allow list by this property may be adjusted over time as the ServiceNow internal network changes. When set to true, glide.ip.authenticate.strict always guarantees an IP allow list that is equal to or more restrictive than the default. When glide.ip.authenticate.strict is set to true: A strict list of ServiceNow IP ranges replaces the default IP allow lists for inbound and outbound requests. This IP allow list, which starts with a more restrictive predefined set of allowed IP ranges, is replaced by the property glide.ip.authenticate.allow.secured.self_hosted_list if the instance is self-hosted. When glide.ip.authenticate.strict is set to false: The default IP allow list is used which contains a wider set of ServiceNow IP ranges. The default IP allow list is replaced by the contents of glide.ip.authenticate.allow.self_hosted_list if the instance is self-hosted. Note: Regardless of the value of glide.ip.authenticate.strict or if the instance is self-hosted, the allow list includes IP addresses in the glide.custom.ip.authenticate.allow and glide.custom.ip.outbound.authenticate.allow system properties, if defined. All IP list properties share the same format, which is a comma separated range of IP addresses in IPv4 or IPv6 format. IP ranges are specified using a hyphen (10.0.10.14-10.0.10.19), using CIDR notation (10.0.10.0/24), or consist of a single IP address (10.0.10.5). At runtime, you can make additions to the IP allow list by adding entries to the IP Address Access Controls [ip_access] table. This table can also be used to explicitly deny IP ranges access to an instance. • Remediation ○ (Old) Ensure the property "glide.ip.authenticate.allow.secured" contains only trusted values and that the property "glide.ip.authenticate.strict" is set to "true".

Documentation	Updates
Enforce secure referrer policy	• Description ○ (Old) <blank> ○ (New) Use the com.glide.security.referrerpolicy system property to control what information is included in the referrer HTTP header across the Now Platform. The data included in the referrer header, according to the policy of this property, is the origin, path, and query strings of the full referrer URL. These values are the standardized Referrer-Policy values supported by the HTTP protocol with the addition of the value "default." Depending on the policy set by this property, the referrer header may include sensitive information about or from the entity making the request. • Remediation ○ (Old) Ensure Glide Property 'com.glide.security.referrerpolicy' is set to 'default'. ○ (New) Ensure that the com.glide.security.referrerpolicy system property is set to one of the following: "default", "same-origin", "origin-when-cross-origin", or "strict-originwhen-cross-origin" • Security Risk ○ (Old) <blank> ○ (New) When the com.glide.security.referrerpolicy system property is set to no-referrer-when-downgrade or unsafe-url, the referrer header of a request to a site different to the origin includes the full URL for the referring page making the request. The full referrer URL shared with external sites may include sensitive information from or about your instance. This can lead to data leakage and privacy violations. When the property is set to no-referrer, origin, or strict-origin, the referrer header

Documentation	Updates
	is either not included, or includes only the origin portion of the referrer URL when requests are sent to the origin. This change may impede efforts to trace attack paths in the logs when a security incident occurs, as the exact origin of a request can't be determined easily. Proper configuration of this property is essential to help prevent unauthorized disclosure of internal identifiers or confidential parameters while allowing for security incident investigations. • Functional Impact ○ (Old) <blank> ○ (New) When the com.glide.security.referrerpolicy system property is set to no-referrer, origin, or strict-origin, the referrer header is either not included, or includes only the origin portion of the referrer URL when requests are sent to the origin. This change can break functionality that requires this data. Some sites like YouTube require embedded link requests to include at least the origin in the referrer header (for example, the "origin-when-cross-origin" policy). The appropriate value of this property is dependent on the instance owner and use case. Those we recommend are described here. These policies are secure and do not break base system functionality. More information of these and the other standardized policies can be found at https://developer.mozilla.org/en-US/docs/Web/HTTP/Reference/Headers/Referrer-Policy. default: Functionally equal to setting the value to same-origin same-origin: Sends the origin, path, and query string for same-origin requests. Doesn't send the referrer header for cross-origin requests. origin-when-cross-origin: When performing a same-origin request, sends the origin, path, and query string. Sends only the origin for cross-origin requests and requests to less secure destinations (from HTTPS to HTTP). strict-origin-when-cross-origin: Sends the origin, path, and query string when performing a same-origin request. For cross-origin requests, sends the origin only when the protocol security level stays same (from HTTPS to

Documentation	Updates
	○ (New) If an email contains more attachments than the allowed count, the attachments are discarded.

Updated hardening settings for baseline version 7.0

Some hardening settings have been updated with the release of Security Center baseline version 7.0.

Documentation	Updates
Enable relay state in SAML requests to prevent replay attacks	• Description: ○ (Old) When "glide.authenticate.sso.saml2.enable_relay_state_with_id" is set to "true", the relay state parameter will contain the sys id of a record in the table multisso_request_parameter which the relay state url to redirect to. This relay state protects against SAML Replay attacks which could be possible in some ServiceNow instance versions if the property glide.authenticate.sso.saml2.enable_relay_state_with_id is set to false. Replay attacks allow a well-positioned attacker who has gained access to the SAML request to resubmit a valid request in orger to gain unauthorized access to the platform. ○ (New) Protect against SAML replay attacks using the glide.authenticate.sso.saml2.enable_relay_state_with_id system property. When this property is set to true, the relay state parameter contains the sys_id of a record in the MultiSSO Request Parameters [multisso_request_parameter] table, which the relay state URL redirects to. Set the system property glide.authenticate.sso.saml2.enable_relay_state_with_id to true. This helps prevent attackers who have gained access to a SAML request from accessing your instance by resubmitting a valid request. The relay state enabled by this system property helps protect your instance against replay attacks. Enabling the property helps prevent attackers

Documentation	Updates
	• Description ○ (Old) ServiceNow instance owners are responsible for provisioning user accounts for their instance and ensuring that users can access the instance in expected ways. When a user, that is not locked out, has a valid password hash on the "sys_user.user_password" field, that user can perform local database authentication for both interactive and non-interactive access types. If a user is also configured to use SSO authentication, local database authentication can still occur without additional controls in place. That is, SSO users with valid local credentials may access the instance, or parts of the instance, with those local credentials. When SSO authentication is enabled for a user, it is best practice to prevent that user from logging in locally. This reduces the chance that the valid local login credentials are stolen and used to login by a malicious user. ○ (New) Users configured to use SSO authentication may be able to access the instance, or parts of the instance, with local credentials stored in the user_password field of their User [sys_user] record. This access applies to both interactive and non-interactive access for users who aren't locked out. Help prevent SSO-configured users from using local credentials to reduce the chance that valid local login credentials are stolen and used by malicious users. Review Now Support Knowledge Base article KB1649420 for instructions on identifying and addressing accounts with local login still enabled on an instance with SSO enabled. • CVSS score ○ (Old) 5.9 ○ (New) 4.2

Documentation	Updates
	specific application data belonging to another user. When properties in this form are set to 'true', an admin level user impersonating another user will not be able to access the application specific data belonging to that user. Not all applications are designed to work in this configuration or ship a 'sys_properties' record for this purpose. A value of "false" for these properties allows an admin level user to impersonate another user and access application data with the impersonated user's access. This may be undesirable or allow for unauthorized data access in specific application contexts. The following scopes contain this property: ▪ sn_opp_market ▪ sn_jny ▪ sn_imt_vaccine ▪ sn_imt_health_test ▪ sn_hr_core ▪ sn_egd_goals ▪ sn_egd_core ▪ sn_egd_act ○ (New) Use system properties to prevent an impersonating user from viewing application data. Prevent admin level from accessing the application specific data belonging to that user when impersonating an account. This permission can be set at the application level by creating a system property specific to the application. These system properties use the .impersonateCheck naming format (for example sn_hr_core.impersonateCheck). Create a system property with a value of true to prevent users from accessing the application-specific data belonging to another user when impersonating an account. NOTE: Not all applications are designed to work in this configuration or have a

	force accounts in a faster timeframe. This property unlocks the user account after the time period that is specified for the glide.user.unlock_timeout_in_mins property. If no value is specified, then the system unlocks the user account after the default period of 15 minutes. If the property is not configured to a secure value and the lockout duration is not enabled, then it may be easier to brute force account logins in a faster timeframe. This may allow a malicious user to eventually obtain unauthorized access to the instance. Impact on the instance will be limited to the privileged of the affected user login brute-forced. • Remediation ○ Set the glide.user.unlock_timeout_in_mins system property value to a minimum of 15. If glide.user.unlock_timeout_in_mins does not exist, the default lockout time is set to 15 minutes. Ensure that the SNC User Lockout Check with Auto Unlock script action (found on the Script Action [sysevent_script_action] table) is present and active. The SNC User Lockout Check with Auto Unlock script action is installed with the High Security Settings (com.glide.high_security) plugin. Ensure the property "glide.user.unlock_timeout_in_mins" is set to "15" or more and that the Script Action (sysevent_script_action) "SNC User Lockout Check with Auto Unlock" is present and active. If the Glide Property "glide.user.unlock_timeout_in_mins" does not exist, it will default to a secure value of "15". The "SNC User Lockout Check with Auto Unlock" is installed with the High Security Plugin. ○ (New) 10
Maximize failed login unlock timeout duration [Updated in Security Center 1.3]	Remediation

Documentation	Updates
	• (Old) Ensure at least one of the script actions: "SNC User Lockout Check" or "SNC User Lockout Check with Auto Unlock" are enabled to manage failed login attempts. Additionally, ensure the property "glide.user.max_unlock_attempts" is set to "5" or less. • (New) Ensure at least one of the script actions: "SNC User Lockout Check" or "SNC User Lockout Check with Auto Unlock" are enabled to manage failed login attempts. These script actions are stored in the "sysevent_script_action" table. Additionally, ensure the property "glide.user.max_unlock_attempts" is set to "5" or less.
Set OTP lifetime for password reset to 1 hour [Updated in Security Center 2.0]	• Short Description ○ (Old) Set OTP Lifetime for Password Reset to 12 Hours or Less ○ (New) Set OTP lifetime for password reset to 1 hour • Description ○ (Old) This property "glide.pwd_reset.onetime.token.validity" allows the link in the password reset email to expire after the number of hours specified in that "glide.pwd_reset.onetime.token.validity" property. Validity time of password reset token should be keeped as short as possible in according of normal user experience. Have long validity time for password reset token can help malicious actors to perform account takeover. ○ (New) Control the time duration of the link in the password reset email. The property glide.pwd_reset.onetime.token.validity makes the link in the password reset email expire after the number of hours

Documentation	Updates
	When the Glide Property 'com.glide.security.protected_table.enabled' is set to 'true', The Protected Tables plugin will be utilized to prevent higher privilege users on an instance from tampering with log tables. The following logging tables will have special protections when this property is set to 'true': ▪ syslog (config not modifiable) ▪ syslog_transaction ▪ sys_outbound_http_log ▪ sysevent ▪ sys_audit ▪ sys_push_notification ▪ protected_table_configuration (config not modifiable) ▪ syslog_app_scope The integrity of logs is important for determining malicious activity on an instance by a customer admin. • Remediation ○ (Old) Set the Glide Property 'com.glide.security.protected_table.enabled' to 'true'. ○ (New) Set the Glide Property 'com.glide.security.protected_table.enabled' to 'true'. This requires a user with the "security_admin" role. • CVSS Score ○ (Old) 4.5 ○ (New) 4
Ensure dashboards creation/deletion requires access check [New in Security Center 1.3 and updated in 2.0]	• Description ○ (Old) The property 'glide.processors.check_access_before_process' enables ACL enforcement for creating or deleting dashboards so long as a user is logged in. Disabling this property (i.e., setting it to false) effectively allows for an ACL bypass on dashboards which allows all authenticated low privileged users to arbitrarily delete and add dashboards. This property should always be set to true.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	○ (New) The property 'glide.processors.check_access_before_process' enables ACL enforcement for creating or deleting dashboards. When the property is set to "true", access control checks are performed on the dashboards. When this property is set to "false", authenticated users can arbitrarily delete and add dashboards. • Remediation ○ (Old) Ensure the Glide Property 'glide.processors.check_access_before_process' exists and is set to the value 'true'. If the property does not appear in the sys_properties table, add a new record. ○ (New) Set the glide.processors.check_access_before_process system property to true. If the property does not appear in the System Properties [sys_properties] table, the fallback value is true. • Security Risk ○ (Old) <blank> ○ (New) When this property is set to "false", authenticated users can arbitrarily delete and add dashboards. • Functional impact ○ (Old) <blank> ○ (New) Users may not have access to delete dashboards as before. To mitigate this functional impact, users can be granted standard access to dashboards. • Fallback Value ○ (Old) false ○ (New) true
Define active session timeout exception roles	• Description ○ (Old)Active session timeouts are a feature to ensure that a hijacked session cannot be used indefinitely without providing authentication information. This property

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	controls the roles that are exempted from an active session timeout limit. It is best practice to only consider an active session timeout limit exception for internal integration account roles. If a role is given an exception to the session timeout, and that role is given to a user who is the victim of a session hijacking attack, an attacker can continue to authenticate to that session indefinitely. This may increase the affected scope of a security incident by allowing an attacker more time to make use of a hijacked account. ◦ (New) Use the glide.active.session.timeout.exception.roles system property to exempt roles from an active session timeout limit. The active session timeout feature helps ensure that a hijacked session can't be used indefinitely without providing authentication information. It is best practice to only consider an active session timeout limit exception for internal integration account roles. Consider an active session timeout limit exception only for internal integration account roles. If a user is a victim of a session hijacking attempt, and has a role with an exception, attackers using that session can continue to authenticate to that session indefinitely. This may increase the impact of a security incident by enabling an attacker more time to make use of a hijacked account. • Remediation ◦ (Old) Ensure Glide Property 'glide.active.session.timeout.exception.roles' is set to value 'edge_encryption,mid_server'. ◦ (New) Configure the glide.active.session.timeout.exception.roles property to roles which should be exempt from active session timeouts. This property value is a comma separated list of roles. The default value is edge_encryption,mid_server,maint.

Updated hardening settings for baseline version 6.0

Some hardening settings have been updated with the release of Security Center baseline version 6.0.

Documentation	Updates
Prevent Unauthenticated Access to Virtual Agent Embedded Web Client	• New Short Description: Prevent Unauthenticated Access to Virtual Agent Embedded Web Client • Old Short Description:Publicly Exposed Virtual Agent Embedded Web Client sn_va_web_client_app_embed
Prevent empty ACL creation	Rule: Script: Script has been updated to improve detection accuracy.
Enable ACLs for Encoded Query in Simple List Widget	• CVSS Score (New): 4.3 • CVSS Score (Old): 5.3
Sanitize All Translated HTML Fields	• CVSS Score (New): 4.6 • CVSS Score (Old): 8.8
Enable HTML Sanitizer [Updated in Security Center 1.3]	Rule Script: Script has been updated to improve detection accuracy
Implement the x-frame-options: SAMEORIGIN security header	• CVSS Score (New): 5.9 • CVSS Score (Old): 7.1
Restrict access to GlideSystemUserSession scriptable API	• Remediation (New): Ensure the property *glide.sandbox.usersession.allow_unsanitize* is set to **false**. If a System Property [sys_properties] record does not exist for this property, create one. • Remediation (Old): Ensure the property *glide.sandbox.usersession.allow_unsanitize* is set to **false**.
Disallow target cloning [New in Security Center 1.3]	• Description (New): If *glide.db.clone.allow_clone_target* is not set to the recommended value of **false**, then the instance can be used as a clone target, or a record that specifies the instance URL and credentials used for cloning. A system clone is when everything in a database is copied from one instance to another. This is a security risk because the instance database can be overwritten in the cloning process,

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	leading to data loss and lack of data integrity. As a remediation, ensure that *glide.db.clone.allow_clone_target* is set to **false**. Not setting this property to the recommended value of false enables the instance to be used as a clone target. This is a security risk because the instance database can be overwritten in the cloning process. • Description (Old): If *glide.db.clone.allow_clone_target* is not set to the recommended value of **false**, then the Instance can be used as a clone target. This risks the instance database being overwritten by cloning process, leading to integrity and availability loss.
Restrict oauth parameters to POST body	• CVSS Score (New): 4.2 • CVSS Score (Old): 7.4
Enforce URL allowlist check	• Description (New): If *glide.security.url.whitelist.strict_check* is not set to the recommended value of **true** then all external URLs are allowed for redirection when *glide.security.url.whitelist* is empty. If *glide.security.url.whitelist* is not empty, then only external URLs in the whitelist are allowed. Thus either setting *glide.security.url.whitelist.strict_check* to true OR ensuring *glide.security.url.whitelist* is set to a non-empty value with the allowed external URLs leaves the instance in a secure state. If all external URLs are allowed for redirection, this could allow an attacker to redirect a user to a malicious website. • Description (Old): If *glide.security.url.whitelist.strict_check* is not set to the recommended value of **true**, and if *glide.security.url.whitelist* is not set to an organization's approved URL, then all external URLs are allowed for redirection. This could allow an attacker to redirect a user to a malicious website.

Documentation	Updates
	• CVSS Score (New): 6.3 • CVSS Score (Old): 8.3
Require XMLdoc2 entity validation with allowlist	• If the **glide.stax.whitelist_enabled** system property does not exist in the System Properties [sys_properties] table, or it is not set to the recommended value of **true**, then all external entities are allowed when the **glide.stax.allow_entity_resolution** system property is set to the value of **true**. If customizations do not require entity expansion, use the **glide.stax.allow_entity_resolution** system property to disable external entity expansion. The XML completes parsing but doesn't include any internal or external entities. ○ If you set **glide.stax.allow_entity_resolution** to **true**, all external entities attempt to resolve or expand subject entities, subject to the setting of the **glide.stax.whitelist_enabled** property. ○ If you set **glide.stax.allow_entity_resolution** to **false**, all entity resolution and expansion is blocked. To learn more about this property, see Disable Entity Expansion within the XMLDocument2 Streaming Parser. When **glide.stax.whitelist_enabled** is set to **true**, define a listing of comma-delimited FQDN in the **glide.xml.entity.whitelist** property, which are the only URLs that can be reached using the XML entity processing property. To learn more, see Restrict XML external entities. Attackers can use this vulnerability to expand data exponentially in an External Entities Expansion (XXE) attack, quickly consuming all system resources. • Description (Old): If *glide.stax.whitelist_enabled* is not set to the recommended value of **true**, then all external entities are allowed. This could lead to External Entities Expansion (XXE) attacks. • Rule Script: Script has been updated to improve detection accuracy

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
Restrict XML external entities	• Protect against XXE attacks by using an allow list to prevent attackers from including arbitrary HTTP requests that the server may execute. This could lead to additional attacks using the server's trust relationship with other entities. Add `http://java.sun.com/j2ee/dtds/` to the value of the **glide.xml.entity.whitelist** system property, then set the **glide.xml.entity.whitelist.enabled** system property to **true**. Values other than `http://java.sun.com/j2ee/dtds/` can be included in the in the **glide.xml.entity.whitelist** property, but are unnecessary for the out of the box platform state. Review any additional values to determine if they are safe. ⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible. • Description (Old): If "glide.xml.entity.whitelist" is not set to the recommended value of "http://java.sun.com/j2ee/dtds/" and "glide.xml.entity.whitelist.enabled" is not set to "true", then a malicious external entity can be allowed which could cause an XXE attack. An attacker can use the DTD to include arbitrary HTTP requests that the server may execute. This could lead to additional attacks using the server's trust relationship with other entities. • Rule Script: Script has been updated to improve detection accuracy
Restrict email domains for external user registration	Rule Script: Script has been updated to improve detection accuracy
Validate file MIME type in AttachmentCreator web service	• Ensure that MIME-types are validated for attachments to prevent dangerous files from being uploaded on your instance using wrong file extensions. Set the **glide.attachment.enforce_security_validation**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	system property to **true**. When set to **true**, files are uploaded with the correct file type extension. • Description (Old): If "glide.attachment.enforce_security_validation" is not set to the recommended value of "true", then there will be no validation for attachment mime-type and dangerous files could be uploaded on the system using wrong file extensions. When this property is set to 'true', files are uploaded with the correct file type extension. It is a security best practice to validate file uploads at least with MIME type validation. • CVSS Score (New): 6.7 • CVSS Score (Old): 7.5
Reduce the scope of the IP allow List for an instance	• Description (New) Prevent unnecessary exposure of instance access to wider group of people using the **glide.ip.authenticate.strict** and **glide.ip.authenticate.allow.secured** system properties. When the **glide.ip.authenticate.strict** system property is set to **true**, internal ServiceNow personnel and systems can only make inbound connections to your instance from essential IP ranges. This limits ServiceNow's visibility to essential internal infrastructure on your instance, and prevents access by broader ServiceNow personnel such as support and sales staff via corporate networks. The **glide.ip.authenticate.allow.secured** system property grants internal ServiceNow inbound connections, including regular authenticated access and unauthenticated diagnostic pages. If not set to **true**, then a broader ServiceNow internal IP range defined in the **glide.ip.authenticate.allow** property is used to grant these internal ServiceNow inbound connections. Ensure the **glide.ip.authenticate.allow.secured** system property contains only trusted values and that the property **glide.ip.authenticate.strict** is set to **true**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	• Description (Old): If "glide.ip.authenticate.strict" is set to "true", then internal ServiceNow personelle and systems can only make inbound connections to the instance from essential IP ranges. This limit's ServiceNow's visibility into the instance to essential internal infrastructure, and prevents access by broader ServiceNow personelle such as support and sales staff via corporate networks. When set to "true", the "glide.ip.authenticate.allow" property is used to grant internal ServiceNow inbound connections. If not set to "true", then a broader ServiceNow internal IP range as defined in "glide.ip.authenticate.allow" is used to grant internal ServiceNow inbound connections.
Disable Entity Expansion within the XMLDocument2 Streaming Parser	• Description (New): Disable entity expansion on your instance to secure your instance from attacks such as ability to read system files, and Denial of Service. Use the system property to disallow XML entities to be expanded during parsing by the streaming parser (XMLDocument2). Set the **glide.stax.allow_entity_resolution** system property to **false** to disable entity expansion on your instance. If this property does not appear in the System Properties [sys_properties] table, the default value is **true**. Create the property record and set the value to **false** to change it's value. • Description (Old): If "glide.stax.allow_entity_resolution" is not set to the recommended value of "False", then this property allow XML entities to be expanded during parsing by the streaming parser (XMLDocument2). XML entity expansion can lead to attacks such as ability to read system files, and Denial of Service. • Remediation (New): Ensure the property *glide.stax.allow_entity_resolution* exists in the sys_properties table and is set to **false**. If the property does not appear in

Documentation	Updates
	the sys_properties list the default value is **true**. • Remediation (Old): Ensure the property "glide.stax.allow_entity_resolution" is set to "false".
Deny by default with empty ACLs	• Description (New): Prevent your instance's legacy security manager from allowing access to resources when there are no ACLs defined for that resource, or if there are only wildcard table-level ACLs (for example, `incident.*`). When allowed access by default, anything that does not have explicit ACLs set is susceptible to manipulation. Set the **glide.sm.default_mode** system property value to **deny** to disallow access when there are no define ACL rules, or there are only wildcard table-level ACLs. • Description (Old): If "glide.sm.default_mode" is not set to the recommended value of "deny", then the instance's legacy security manager allows access to a resource when there are no ACLs defined for that resource; or only wildcards table-level ACLs. By setting this to "allow" anything that does not have explicit ACLs set is susceptible to manipulation. • CVSS Score (New): 6.3 • CVSS Score (Old): 8.8 • Rule Script: Script has been updated to improve detection accuracy
Restrict unauthenticated access to attachments	• Description (New): Secure the images on your instance to prevent sensitive information leak. Images on your instance are accessible via urls that end in `.iix`. Set the **glide.image_provider.security_enabled** system property to **true** to prevent access to your images via these URLs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	Note: This property is not honored for images from the attachment table if the origin table is one of: ○ Stationeries [sysevent_email_style] ○ Welcome Page Sections [sys_home] ○ System Properties [sys_properties] Restriction should be applied for unauthenticated users as some attachments might contain sensitive information. • Description (Old): If "glide.image_provider.security_enabled" is not set to the recommended value of "True", then all images are accessible via urls that end in ".iix". This would allow unauthenticated access to images leading to sensitive information leak.
	• Description (New): Disable support for displaying HTML code embedded using the `[code]` tag. This tag allows rendered HTML to display in journal fields and may lead to cross-site scripting (XSS) attacks. These attacks can enable foreign scripts to execute on a user session in the logged in browser's context. Attackers can use these scripts to steal session information and sensitive data. The HTML language was not designed to separate script from formatting, so allowing user-controlled HTML in any system has inherent risk. Setting the **glide.ui.security.codetag.allow_script** to **false** is compliant, and significantly reduces this risk, however some small risk remains. It disables only the script portion of a `code` tag, and relies on sanitizing all known conventions of script in the HTML. Set the **glide.ui.security.allow_codetag** system property to **false** to completely prohibit journal fields and forms from displaying rendered HTML.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.

Documentation	Updates
	The ServiceNow AI Platform mitigates many injection and cross-site attacks by implementing escaping and encoding techniques. As a result, users can't write/submit HTML formatted inputs for journal fields. But journal fields can render text enclosed within code tags as HTML. ○ However, there is an associated security risk. If set to `true`, malicious users can write harmful HTML JS code that may be executed on a different client browser after rendering of journal fields. ○ Set this property to `false` so that administrators can prevent journal fields from rendering HTML code by disabling support for the `[code]` tag. • Description (Old): Disables support for embedding HTML code created using the [code] tag. If "glide.ui.security.allow_codetag" is not set to the value of "false", then rendered HTML in journal fields and forms will not be displayed. Setting "glide.ui.security.allow_codetag" to "true" with display embedded HTML code with may lead to cross-site scripting (XSS) attacks.
Enable password reset policy checks	Rule Script: Script has been updated to improve detection accuracy
Enable email spam scoring and filtering	• Technical Configuration Name (New): com.glide.email_filter,glide.email.read.active • Technical Configuration Name (Old): com.glide.email_filter • Rule Script: Script has been updated to improve detection accuracy
Escape Excel formulas	• Description (New): Prevent potentially malicious formulas in programs such as Excel from being executed after exporting and opening the file by escaping formulas in these files. Excel injection occurs when websites embed untrusted entries inside Excel files. When you use a spreadsheet application such as Microsoft Excel, or LibreOffice Call, to open a file, any cells starting with +, -, =, or @ are interpreted as a formula unless properly

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	escaped. Malicious formulas pose a risk even when the spreadsheet doesn't contain any sensitive information, as they can be used to compromise the viewer's computer through code execution. Set the **glide.export.escape_formulas** system property to **true** to escape these formulas from executing. • Description (Old): Setting the property "glide.export.escape_formulas" to the recommended value of "true" prevents potentially malicious formulas in programs such as Excel from being executed after exporting and opening the file. Cell values for CSV, Xls, and XLSX can be interpreted as formulas by spreadsheet applications unless properly escaped which can lead to malicious code execution. • CVSS Score (New): 6.4 • CVSS Score (Old): 6.5
Restrict JSONP requests to trusted URLs	• Description (New): Increase security on your instance by ensuring that only trusted URLs for the AngularJS $http service can allow/reject JSONP requests. JSONP requests are allowed to any URL if these properties are not configured and enabled. Use the value of the **angular.jsonp.inclusion_list.urls** system property to define a list of URLs that are trusted and allow for this purpose. Set the value of the **angular.jsonp.inclusion_list.enabled** system property to **true** to limit allowed JSONP to only the URLs listed in **angular.jsonp.inclusion_list.urls**. • Description (Old): This property specifies trusted URLs for the angularJS $http service to allow/reject JSONP requests. Property is necessary because this is a potentially breaking change for customers, so they need a way to add their trusted URLs. If "angular.jsonp.inclusion_list.enabled" is not set to the recommended value of "true", then JSONP requests are allowed to any URL.

Documentation	Updates
Enable SNC access control plugin	• Description (New): Prevent ServiceNow Customer Service and Support personnel from accessing the instances without your express permission by enabling the SNC Access Control (com.snc.snc_access_control) plugin. Although all access to your instance is audited, you may prefer to control this access. This access method is fully auditable and tracked. **Note:** Other authorized ServiceNow Operations personnel, in their capacity to support and manage the product, are required to perform administrative actions on the underlying infrastructure. Enabling this plugin may affect support service levels and the Availability SLA. Availability SLA is then measured from the time that Support staff personnel are granted access to your instance. Enable the SNC Access Control (com.snc.snc_access_control) plugin to restrict access to your instance without your express permission. For more details on this feature, see ServiceNow access control. For activation information, see Activate ServiceNow access control • Description (Old): The SNC Access Control (com.snc.snc_access_control) plugin prevents Customer Service and Support personnel from accessing the instances without your express permission. However, other authorized ServiceNow Operations personnel, in their capacity to support and manage the product, are required to perform administrative actions on the underlying infrastructure. This infrastructure includes servers and databases, among other infrastructure components that make up the SaaS solution. This access method is fully auditable and tracked.This plugin enables you to restrict access to your instance without your express permission, so it may affect support service levels and the Availability SLA. Availability SLA is then measured from the time that Support staff personnel are granted access to your instance.

Documentation	Updates
	• Remediation (New): Ensure the plugin "com.snc.snc_access_control" is activated. Read the documentation on activating at https://www.servicenow.com/docs/csh?topicname=t_ActivateSNCAccessControl.html&version=lates • Remediation (Old): Ensure the plugin "com.snc.snc_access_control" is activated. • CVSS Score (New): 3.3 • CVSS Score (Old): 8.2
Maximize failed login unlock timeout duration [Updated in Security Center 1.3]	• Technical Configuration Name (New): glide.user.unlock_timeout_in_mins, sysevent_script_action • Technical Configuration Name (Old): glide.user.unlock_timeout_in_mins • Description (New): Help secure your instance against brute force attacks by defining a time period during which a user cannot attempt to log in after being locked out. The **glide.user.unlock_timeout_in_mins** system property unlocks the user account after the time period that is specified in it's value. If no value is specified, your instance unlocks the user account after the default period of 15 minutes. • Description (Old): If "glide.user.unlock_timeout_in_mins" is not set to the recommended value of "15", then it may be easier to brute force accounts in a faster timeframe. This property unlocks the user account after the time period that is specified for the glide.user.unlock_timeout_in_mins property. If no value is specified, then the system unlocks the user account after the default period of 15 minutes. • Remediation (New): Set the **glide.user.unlock_timeout_in_mins** system property value to a minimum of **15**. If **glide.user.unlock_timeout_in_mins** does not exist, the default lockout time is set to 15 minutes. Ensure that the **SNC User Lockout Check with Auto Unlock** script action (found on the Script Action [sysevent_script_action] table) is present and active. The **SNC User**

Documentation	Updates
	Lockout Check with Auto Unlock script action is installed with the High Security Settings (com.glide.high_security) plugin. • Remediation (Old): Ensure the property "glide.user.unlock_timeout_in_mins" is set to "15" or more. • Rule Script: Script has been updated to improve detection accuracy
Restrict access to specific IP ranges plugin	• Technical Configuration Name (New): com.snc.ipauthenticator,ip_access • Technical Configuration Name (Old): com.snc.ipauthenticator
Restrict access to emails with empty target table	• CVSS Score (New): 6.5 • CVSS Score (Old): 5.4
Restrict downloadable MIME types	• CVSS Score (New): 6.4 • CVSS Score (Old): 8
	• Technical Configuration Name (New): glide.authenticate.multissov2_feature.enabled • Technical Configuration Name (Old): glide.authenticate.multisso.enabled,glide.authenticate.multiss • Description (New): If the Multi SSO plugin is enabled on an instance, reduce security vulnerabilities by confirming that the v2 version is enabled. The latest version enhances security and has more features, such as Assertion encryption support, and IDP-initiated Single Logout (SLO). If the latest version is not enabled, the new security features cannot be used and the instance is at risk of using an plugin which is deprecated. Follow the steps in KB0756504 to upgrade to the latest version. This process includes checking for and migrating any customization-related changes, then upgrading the version. When complete, the **glide.authenticate.multissov2_feature.enabled** system property is automatically set **true**. • Description (Old): If the Multi SSO plugin is enabled on an instance, the v2 version should be enabled. Versions prior to

Documentation	Updates
	MultiSSOv2, including SAML 1.1 and SAML 2.0, do not follow best practice and use opensaml library versions with known CVEs. If the known CVEs were exploitable in outdated opensaml libraries, this could allow the attacker to forge messages and bypass authentication through XML Signature Wrapping attacks, impersonate entities or allow person-in-the-middle attackers to gain unauthorized access to the platform. • CVSS Score (New): 0 • CVSS Score (Old): 7.1
Prevent inactive users from logging in	Rule Script: Script has been updated to improve detection accuracy
Enable MID audit log	Rule Script: Script has been updated to improve detection accuracy
Ensure archive table ACLs are checked	Rule Script: Script has been updated to improve detection accuracy
Define active session timeout exception roles	• CVSS Score (New): 6.4 • CVSS Score (Old): 7.1
Limit HTTP response body size [New in Security Center 1.3 and updated in 1.5]	• Description (New): Prevent `OutOfMemoryExceptions` that can result from a request response body being too large using the **glide.http.response.get_body.limit.enabled** and **glide.http.response.get_body.limit** system properties. These exceptions can cause denial of service (DOS) attacks as well as other issues that may aid attackers in compromising an instance. Not setting these properties to the recommended values could make your instance vulnerable to OutOfMemoryExceptions and denial of service attacks. To protect your instance against these security vulnerabilities: ○ Set the **glide.http.response.get_body.limit.enabled** system property to **true**. ○ Ensure that the **glide.http.response.get_body.limit** system property set to no more than 524,288,000 megabytes (500 MB). • Description (Old): The properties glide.http.response.get_body.limit.enabled

Documentation	Updates
	and glide.http.response.get_body.limit were introduced to enable new functionality that prevents Out of memory exceptions being thrown as a result of a requests response body being too big. Out of memory exceptions can cause denial of service attacks as well as other issues that may aid attackers in compromising an instance. • CVSS Score (New): 3.1 • CVSS Score (Old): 6.4
Limit UI active session life span	• Description (New): Reduce the scope of potential security incidents by decreasing the lifespan of active HTTP sessions. The **glide.ui.active.session.life_span** system property enforces a maximum lifespan on active HTTP sessions irrespective of inactive timeout. Longer maximum lifespans can allow an attacker to use a stolen session a for longer time, increasing the scope of a security incident. The default value of **0** disables timeout of active sessions Set the **glide.ui.active.session.life_span** to a value between 1 and 720. This value represents the time in minutes that HTTP sessions can remain active. • Description (Old): This configuration will enforce max lifespan on active guest HTTP sessions irrespective of inactive timeout. The configured value is in minutes and the value of zero will disable timing out the active sessions. A larger maximum lifespan could allow an attacker to persist a stolen session for longer, increasing the scope of a security incident. This particular property is limited to UI session timeout.

Updated hardening settings for baseline version 5.0

Some hardening settings have been updated with the release of Security Center baseline version 5.0.

Baseline version 5 includes several updates to short descriptions for style and consistency across records. In addition, many property related scripts were updated to improve the accuracy of default values in cases where the property has been removed from the sys_property table.

Documentation	Updates
	• Old remediation: Ensure the property *glide.ui.attachment.force_download_all_mi* is set to true. • Rule Script: Script has been updated to improve detection accuracy.
Define restricted downloadable MIME types	Rule Script: Script has been updated to improve detection accuracy.
Disallow infected file download	• New description: When the property *com.glide.snap.infected_download_allowed* is set to true, users can still download non-scanned attachments in the case that the antivirus service is down or unreachable. This means it is possible that a user downloads a malicious file and risks infecting the user's desktop (in the case there is no other endpoint protection on the device). • Old description: If *com.glide.snap.infected_download_allowed* is not set to the recommended value of False, then it is possible to download a malicious file that has not been scanned leading to a risk of infecting the user's desktop. • New remediation: Ensure the property *com.glide.snap.infected_download_allowed* is set to false. • Old remediation: Ensure the property *com.glide.snap.infected_download_allowed* is set to False.
Restrict access to GlideSystemUserSession scriptable API	• New description: *gs.addErrorMessageNoSanitizationMessaging(* and *gs.addInfoMessageNoSanitization()* are used within the scripting environment for logging and notifications. Both of these are available in the sandbox if this property is not set to the recommended value of false. The sandbox is a low privileged scripting environment available to unauthenticated and no role users. Both of these methods can be used to display unsanitized input to a user. Displaying unsanitized input to the user is dangerous, as unsanitized input may contain dangerous code that runs in the user's browser. This can be utilized for traditional reflected XSS attacks. Reflected XSS attacks can be used

Documentation	Updates
	in multiple scenarios, including session hijacking. • Old description: Messaging within the glide scripting sandbox is used for logging purposes. Calling this unsanitized error function exposes the platform to reflected XSS attacks. XSS attacks can allow for easy privilege escalation by stealing someone's session cookies. If `glide.sandbox.usersession.allow_unsanitize` is not set to the recommended value of false, then the unsanitized error messaging functions `addErrorMessageNoSanitization` and `addInfoMessageNoSanitization` are available to script.
Enable work order management query rules for service organizations	• New description: When set to true, rules/ filters from sn_query_rule table will be used to determine read access to Field Service Management-related tables (Work Order and Work Order Task) to the logged in user through query business rules and read ACLs. When false, the records won't be filtered based on query rules. Query business rules add additional security validations. Specifically, this property will filter records for agents, qualifiers, and dispatchers based on their assigned territory or territory membership. It is best practice to follow the principle of least privilege when reading records. When this property is not set to true, there may be increased risk of data exposure from Field Service Management tables. • Old description: When set to true, rules/ filters from sn_query_rule table will be used to determine read access to Field Service Management-related tables (Work Order and Work Order Task) to the logged in user through query business rules and read ACLs. When false, the records won't be filtered based on query rules. Query business rules add additional security validations. Documentation	Updates
Verify certificate chain and hostname	• New description: When the Glide Property *com.glide.communications.httpclient.verify* is not set to the secure value of true, the hostname and certificate chain presented by remote hosts during a TLS connection initiated from the ServiceNow instance are not validated. This could compromise the security of the TLS connection and allow person-in-the-middle attacks, where communications between two parties are intercepted. This may lead to sensitive data disclosure. • Old description: If *com.glide.communications.httpclient.verify* is not set to true this could allow person-in-the-middle attacks where communications between two parties are intercepted. Setting this property to an insecure value disables the certificate verification process which evaluates all certifications in the certificate chain through checking revocation status. Set this property to true to prevent the http client from connecting to a potentially harmful hostname.
Control lockout time for invalid password reset attempts	• New short description: *Control Lockout Time for Invalid Password Reset Attempts* • Old short description: *Minimize Reset Password Request Max Attempts Window Duration* • New description: The *password_reset.request.max_attempt_window* property defines the number of minutes a user must wait to reset or change their password after exceeding the maximum number of unsuccessful attempts that is set with the *password_reset.request.max_attempt property*. A small number of minutes for the *password_reset.request.max_attempt_window* property increases the risk of successfully brute forcing a password as a greater number of password reset attempts can be made. The default of 1440 minutes is recommended. • Old description: If *password_reset.request.max_attempt_window* is not set to the recommended value of 1440 or less, then it could be possible to perform

Documentation	Updates
Require authorization for SOAP requests	• New technical configuration name: *glide.basicauth.required.soap, glide.soap.require_ws_security* • Old technical configuration name: *glide.basicauth.required.soap* • New description: The glide property *glide.basicauth.required.soap* controls whether basic authentication is required to make a SOAP request to an instance. If *glide.basicauth.required.soap* is not set to the recommended value of true, then unauthenticated users performing SOAP operations will be mapped to the soap.guest user. This may enable an unauthenticated user to perform operations on the instance as if a logged in user to the instance. There may be additional impact if the user define within *com.glide.soap.guest_user* is assigned additional roles. • Old description: The glide property *glide.basicauth.required.soap* controls whether authentication is required to make a SOAP request to an instance. If *glide.basicauth.required.soap* is not set to the recommended value of true, then authentication is disable for SOAP requests on the instance. It allows unauthenticated access to administrator or maint level operations; thereby negating security controls within the instance. • New remediation: Ensure the property *glide.basicauth.required.soap* is set to the value true. Alternatively, configure the instance for WS Security by setting the property *glide.soap.require_ws_security* to true and following the product documentation to configure WS Security Profiles. • Old remediation: Ensure the property *glide.basicauth.required.soap* exists in the sys_properties table and is set to true. • Rule Script: Script has been updated to improve detection accuracy.

Documentation	Updates
Escape jelly script	• New description: This property escapes all the JS and HTML strings included in before they are written to the output stream, preventing several XSS issues from occurring. If *glide.ui.escape_all_script* is not set to the recommended value of true, then escaping of scripts injected into Jelly is disabled. Without this mitigation, the platform becomes widely open to a variety of script injection attacks. An attacker could execute arbitrary Rhino scripts on the instance. • Old description: The following property escapes all the JS and HTML strings included in <j:jelly> ... </j:jelly> before they are written to the output stream, preventing several XSS issues from occurring. If *glide.ui.escape_all_script* is not set to the recommended value of "true", then escaping of scripts injected into Jelly is disabled. Without this mitigation, the platform becomes widely open to a variety of script injection attacks. An attacker could execute arbitrary Rhino scripts on the instance.
Prevent Users From Accepting Warning To Bypass CSRF Validation [Updated in Security Center 1.3 and 1.5]	• New short description: Prevent Users From Accepting Warning To Bypass CSRF Validation • Old short description: Enforce CSRF Token Strict Validation • New description: This property prevents users from being able to accept a warning which allows a potentially malicious request to be sent to the instance. This warning appears when a POST request fails due to having a mis-matched anti-CSRF token belonging to one of the victim's other active sessions. If *glide.security.csrf.strict.validation.mode* is not set to the recommended value of true, then an attacker can formulate a CSRF attack utilizing a leaked anti-CSRF token from a different active session belonging to the victim.A POST request to an instance contains an anti-CSRF token within sysparm_ck or X-UserToken which matches the user's current session. If the anti-CSRF token is instead tied to one of the user's other active sessions, the POST request will return a 302 redirection to

Documentation	Updates
	security_interceptor.do with a Continue button available to the user when this property is set to false. Clicking this button will re-submit the request to the instance, except it will now having a valid anti-CSRF token. When this property is set to true, the 302 redirection to the security_interceptor.do page will not display a Continue button and the user will not be allowed to resubmit the request.A successful CSRF attack will allow an attacker to effectively perform any operation that the victim is able to perform. • Old description: This property enables CSRF token strict validation which prevents the reuse of CSRF tokens. If *glide.security.csrf.strict.validation.mode* is not set to the recommended value of true, then CSRF tokens could be reused which opens a door to CSRF attacks. • New CVSS Score: 3.7 • Old CVSS Score: 3.1
Require Authentication on Event Management HTTP Processor [New in Security Center 1.3, Updated in 1.5, and removed in 2.0]	• New short description: Require Authentication on Event Management HTTP Processor • Old short description: Require Authentication on Event Management HTTP Processor
Enable anti-CSRF token	• New description: Cross-Site Request Forgery (CSRF) is an attack that forces authenticated users to submit a request to a Web application against which they are currently authenticated. CSRF attacks exploit the trust a Web application has in an authenticated user. This property enables usage of a secure token to identify and validate incoming requests. This token is used to prevent cross site request forgery attacks. If *glide.security.use_csrf_token* is not set to the recommended value of true, then CSRF is possible. • Old description: Cross-Site Request Forgery (CSRF) is an attack that forces authenticated users to submit a request to a Web application against which they are currently authenticated. CSRF attacks exploit the trust a Web application has in an authenticated user. This property enables usage of

Documentation	Updates
	a secure token to identify and validate incoming requests. This token is used to prevent cross site request forgery attacks. If *glide.security.use_csrf_token* is not set to the recommended value of true, then CSRF is possible.
Enable HTML sanitizer within Virtual Agent	• New short description: Enable HTML Sanitizer within Virtual Agent • Old short description: Enable HTML Sanitizer • New description: This property controls the whether the HtmlSanitizerService is enabled. If *com.glide.cs.html.sanitizer.enabled* is not set to true, then a Stored Cross-Site Scripting (XSS) attack is possible in the VA web client. • Old description: This property controls the whether the HTMLSanitezerService is enabled. If *com.glide.cs.html.sanitizer.enabled* is not set to true, then a Stored Cross-Site Scripting (XSS) attack is possible in the VA web client.
Deny internal access to explicit external roles [Updated in Security Center 1.3 and 1.5]	• New technical configuration name: *glide.security.explicit_roles.enable_intei* • Old technical configuration name: *glide.security.explicit_roles.enable_intei* • New description: This property prevents external users from being assigned the snc_internal role. When *glide.security.explicit_roles.enable_intei* is set to the recommended value of true, then it enforces the parameters of the maint-protected *glide.security.explicit_roles.internal_use property* which assigns the snc_external role to a list of untrusted user classes. If the value is set to false, the *glide.security.explicit_roles.internal_use* property is ignored. Misconfiguration of this propery increases the risk that an external user account gains access to internal information. • Old description: This prevents external users from being assigned the snc_internal role. If *glide.security.explicit_roles.enable_intei*

Documentation	Updates
	is not set to the recommended value of true, and the *glide.security.explicit_roles.internal_use* property is not set to a list of untrusted user classes, then the specified roles can be assigned the snc_internal role instead of the snc_external role. If the list is empty, then all users will be assigned the snc_internal role by default. The property should contain at least the default roles csm_consumer_user, customer_contact. Misconfiguration of these properties increases the risk that an external user account gains access to internal information. • New remediation: Ensure the property *glide.security.explicit_roles.enable_inte* is set to true. • Old Remediation: Ensure the property *glide.security.explicit_roles.enable_inte* is set to true and that the property *glide.security.explicit_roles.internal_use* includes the dangerous items csm_consumer_user, customer_contact. • Rule Script: Script has been updated to improve detection accuracy.
Require authorization for WSDL request	• New description: If *glide.basicauth.required.wsdl* is not set to the recommended value of true, then this will disable Basic Authentication for WSDL requests. WSDL is a protocol that is used to describe web services such as instance table schemas, and is not a mechanism for sharing the data within tables. Setting this property to true allows for disclosure of table schemas to unauthenticated users. • Old description: If *glide.basicauth.required.wsdl* is not set to the recommended value of true, then this will disable Basic Authentication for WSDL requests. This could lead to information disclosure to unauthenticated users. • New CVSS Score: 5.3 • Old CVSS Score: 4.3

Documentation	Updates
Disable Multi-SSO debugging	• New short description: Disable MultiSSO Debugging • Old short description: Disable MultiSSO Debugging (Plugin Applicability: Multiple Provider Single Sign-On)
Reduce the scope of the IP allow List for an instance	• New technical configuration name: *glide.ip.authenticate.strict* • Old technical configuration name: *glide.ip.authenticate.strict,glide.ip.auth* • New description: If *glide.ip.authenticate.strict* is set to true, then internal ServiceNow personelle and systems can only make inbound connections to the instance from essential IP ranges. This limit's ServiceNow's visibility into the instance to essential internal infrastructure, and prevents access by broader ServiceNow personelle such as support and sales staff via corporate networks. When set to "true", the *glide.ip.authenticate.allow* property is used to grant internal ServiceNow inbound connections. If not set to true, then a broader ServiceNow internal IP range as defined in *glide.ip.authenticate.allow* is used to grant internal ServiceNow inbound connections. • Old description: If *glide.ip.authenticate.strict* is set to true, then only IP ranges specified in *glide.ip.authenticate.allow.secured* can make inbound connections to the instance. This property contains a list of only essential ServiceNow internal IP ranges (Secure VPN, DC). If *glide.ip.authenticate.allow.secured* is not set to the recommended value or permutation of "10.0.0.0/8, 37.98.232.0/21, 103.23.64.0/22, 149.96.0.0/17, 149.96.0.0/16, 199.91.136.0/21, 148.139.0.0/16, 127.0.0.1" or the newer value list "10.0.0.0/8, 37.98.232.0/21, 103.23.64.0/22, 149.96.0.0/17, 149.96.0.0/16, 199.91.136.0/21, 148.139.0.0/16, 127.0.0.1, 0:0:0:0:0:0:0:1, ::1" which adds IPv6 localhost to Utah, then it may allow untrusted sources outside of SN DataCenter and secure VPN to access sensitive monitoring endpoints on instances.

Deleted hardening settings

Some hardening settings are removed from Security Center baselines.

Deleted hardening settings for baseline version 9.0

Some hardening settings have been removed with the release of Security Center baseline version 9.0.

- Restrict access to specific IP ranges plugin
- Hide user comments on articles
- Disable embedded HTML code

Deleted hardening settings for baseline version 8.0

Some hardening settings have been removed with the release of Security Center baseline version 8.0.

- Certificate Based Authentication Not Enforced
- Enable Updated Version of Multi SSO Plugin
- Set Allowed MIME Child Types

Deleted hardening settings for baseline version 7.0

Some hardening settings have been removed with the release of Security Center baseline version 7.0.

- Disable Password-Less Authentication
- Escape XML Response
- Minimize One-Time Out of Band Verifier Lifetime Duration

Deleted hardening settings for baseline version 6.0

Some hardening settings have been removed with the release of Security Center baseline version 6.0.

- Enforce ACL on HR Lifecycle Events Data
- Enforce Security Scope License and Permit Playbook
- Enforce ACL on HR Core Data
- Restrict Global Administrators from Bypassing Scoped App Access Restrictions
- Disable Legacy AngularJS Behavior
- Enforce Field Level ACLs in GlideRecordSandbox
- Enforce Scope Security for Public Sector Digital Services

- Restrict Downloadable Files Types in Static Content
- Enforce Scoped ACL Access for Information Request Playbooks
- Minimize SAML "notBefore" or "notOnOrAfter" Constraint Duration
- Restrict Delegated Developers Read Access
- Enforce Password Policy on All Methods
- Enforce Security Scope for Service Application Information
- Require Obfuscation of Classic Mobile App UI
- Enable SSL in LDAP Authentication
- Enforce Security Scope for Agent Workspace for HR Case Management
- Limit Attachment Size in Training and Prediction Flows
- Remove Credentials From Welcome Page
- Enforce ACL on HR Virtual Agent Data
- Check Impersonation on ACL Evaluation in HR App
- Restrict Allowed Java Packages
- Enforce Strict Code Signing Checks

Deleted hardening settings for baseline version 5.0

Some hardening settings have been removed with the release of Security Center baseline version 5.0.

- Require Authentication on Event Management HTTP Processor
- Restrict Access to Custom Journal Entries
- Do Not Apply Password Policy at Login
- Disable Raw Database Query Execution
- Log HTML Sanitization
- Enable Anti-CSRF Token
- Enforce Certificate Trust
- Unset LDAP Initial Distinguished Name
- Set Minimal Password Length

Deleted hardening settings for baseline version 4.0

Some hardening settings have been removed with the release of Security Center baseline version 4.0.

- LDAP Initial Password
- Mobile Offline Roles
- Restrict Access to Critical Data through Zero Trust Access Policies (Plugin Applicability: Adaptive Authentication)
- Read Only Tables Allowlist For Write
- Allowed JDBC Probe Operations (Plugin Applicability: MID Server)
- Set Allowed Domains which Create Users from Incoming Emails
- Set Complex "Default" Password

- Accessible Properties in GraphQL Allowlist
- Cross Origin Messaging Allowlist
- Limit Attachment Size in Training and Prediction Flows for GraphQL Enpoints (Plugin Applicability: Platform Document Intelligence)
- Edit Content Roles Allowlist (Plugin Applicability: Communities)
- Ensure Database Queries Do Not Trigger a OutofMemory Exception Due to Query Size
- Role Allowlist for Script Execution
- Downloadable File Type Allowlist
- Read Only Tables Allowlist For Delete
- Enforce Authentication for Roleless ACL
- Minimize LDAP One-Time Token Expiry Time
- Allow Only Trusted IP Addresses for Authentication
- Set Mobile Password Reset URL
- Password Complexity of Service Accounts (Plugin Applicability: Service Bridge)
- Notify Users During Password Reset/Change Process
- Enforce Application Scope Restrictions
- Access Control Requirements (Plugin Applicability: Communities)
- Record History Access Role Allowlist
- Restrict Role Access for Attachments
- Only Allow PDFs from Predefined List of Trusted URLs
- Prevent Emailing One-Time Password During LDAP Server Outage
- Convert Inbound Email Images to Attachments
- Review Extraneous Explicit Role Access Control Condition

Deleted hardening settings for baseline version 2.0

Some hardening settings have been removed with the release of Security Center baseline version 2.0.

- Enable Code Signing for Application Configuration Data and Scripts
- Enable Glide KMF encrypter
- Disable the Use of Instance Level Encrypter
- Enable Explicit Roles Internal Denylist
- Block Direct Inserts to MID ECC Queue for Code Signing Requirement
- Log All Outbound HTTP Request Fields

Access control

The access control category audits the process of protecting resources from unauthorized access through granting and denying requests based on a permission model. This includes ensuring an entity accessing a resource holds valid credentials to do so, creating and protecting a well-defined set of roles or permissions and ensuring role or permission controls are protected from replay and tampering.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Access controls determine whether access to a particular resource should be granted or denied. It only allows access to resources to those users permitted to use them.

Anti-CSRF token validation time

The *glide.security.csrf_previous.time_limit* property specifies the time in seconds for a secure token to expire.

The *glide.security.csrf_previous.time_limit* system property determines the time in seconds for a secure token to expire. When the user session expires, the secure token expires with it, unless the **allowing reuse of expired tokens** property is enabled, and its within the time frame described by this property. This token is used to prevent cross site request forgery attacks.

Ensure that the *glide.security.csrf_previous.time_limit* property is set to `86400` seconds (1 day).

More information

Attribute	Description
Configuration name	*glide.security.csrf_previous.time_limit*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	86400
Default value	86400
Fallback value	86400
Category	Access control
Security risk	• Severity score: 5.3 • CVSS score: Medium • Security risk details: The time limit for a CSRF token to expire defines how long the token remains valid for verifying legitimate user requests; if set too long, it increases the risk that an attacker could reuse a stolen token to perform unauthorized actions, while a shorter expiration window reduces this risk by narrowing the attack window.
Dependencies and prerequisites	None
Functional impact	This property determines the duration in seconds for a secure token to remain valid. The secure token expires when the user session expires unless the **allowing reuse of expired tokens** property is enable, and the token is within the time frame specified in this property. This token prevents cross-site request forgery attacks. It has a default value of 86400 seconds or 1 day.

Apply domain separation on dot walked fields

The *glide.sys.domain.include_domain_condition_on_join* property controls whether join queries are given domain separated conditions or not in order to ensure they apply domain separation functionality for dot walked fields.

The *glide.sys.domain.include_domain_condition_on_join* system property controls whether join queries are given domain separated conditions or not, in order to ensure they apply domain separation functionality for dot walked fields.

Ensure that the property *glide.sys.domain.include_domain_condition_on_join* is set to **true** when the Domain Separation plugin is active.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.sys.domain.include_domain_condition_on_join*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true **Note:** If domain separation is installed, otherwise the property doesn't exist.
Default value	false
Fallback value	false
Category	Access control
Purpose	Controls whether join queries are given domain separated conditions or not, to confirm they apply domain separation functionality for dot walked fields.
Security risk	• Severity score: 6.5 • CVSS score: Medium • Security risk details: Sensitive information could be disclosed that is not to be shared with a specific domain.
Functional impact	There may be moderate functional impact to the instance if components are reliant on the unsafe cross domain queries. Instances should be tested in non-production environments before enabling.
References	Domain separation for service providers

Block access for delegated developers

This configuration affects access for delegated developers that are updating user roles through script. When the configuration is compliant, the developer will not be able to update or insert records into the sys_user_has_role table without also having the user_admin role.

This property determines whether a delegated developer can give assign roles to users through scripts. If *com.glide.sys.security.delegateddev.block_grant_roles* is not set to the recommended value of **true**, then a delegated developer could assign roles to any user. This could lead to unapproved privilege escalation.

Ensure that the property *com.glide.sys.security.delegateddev.block_grant_roles* is set to **true**.

More information

Attribute	Description
Configuration name	*com.glide.sys.security.delegateddev.block_grant_ro*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Access control
Security risk	• Severity score: 6.7 • CVSS rating: Medium • Security risk details: Delegated developers may assign roles to any user via scripts, posing a significant security risk of unauthorized privilege escalation.
Functional impact	When a user with the delegated_developer role is attempting to modify a record in the User Roles [sys_user_has_role] table, this property enables additional security checks against the operation. The additional security checks validate that the user has been granted the user_admin role if they're trying to create or update the User Roles [sys_user_has_role] table. If they do not have the user_admin role, the access will be denied. When the property is false, these additional checks are not validated.
Dependencies and prerequisites	None

Block Expired Anti-CSRF Tokens

Block expired CSRF tokens to prevent cross-site request forgery attacks.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The *glide.security.csrf_previous.allow* system property enables use of an expired secure token to identify and validate incoming requests. This token is used to prevent cross-site request forgery attacks.

Ensure that the property *glide.security.csrf_previous.allow* is set to **false**.

More information

Attribute	Description
Configuration name	*glide.security.csrf_previous.allow*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	true
Category	Access control
Security risk	• Severity score: 6.5 • CVSS rating: Medium • Security risk details: Allowing the use of previous or expired CSRF tokens exposes the application to replay attacks, enabling attackers to reuse valid requests and potentially perform unauthorized actions on behalf of legitimate users.
Functional impact	None
Dependencies and prerequisites	None

Check UI action conditions before execution

Use the *glide.security.strict.actions* property to enable checking of UI actions conditions in forms and lists before they execute. When you set this property to true, it adds an extra layer of validation on the table UI actions before they are executed.

If the *glide.security.strict.actions* system property isn't set to the recommended value of **true**, then there is no validation on the table UI before execution. Setting this property to secure value adds an extra layer of security validation.

Ensure that the property *glide.security.strict.actions* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.security.strict.actions*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Default value	TRUE
Fallback value	true
Category	Access control
Security risk	• Severity score: 3.3 • CVSS rating: Low • Security risk details: Users may perform unauthorized operations, leading to data manipulation, privilege escalation, and bypassing of access controls protecting sensitive records.
Functional impact	This remediation only adds an extra layer of validation to check for UI actions on the target table/page on the instance. As long as the access controls are set appropriately on the customer instance, there should not be an impact here.
Dependencies and prerequisites	None

Configure event management assignment group admin roles [New in Security Center 1.5]

Use the *evt_mgmt.connector_assignment_group_admin_roles* property to set which roles are authorized for admin access over the assignment group field in connector instances.

The *evt_mgmt.connector_assignment_group_admin_roles* property contains a comma separated string which indicates the role names that have admin access over the assignment group field in connector instances. Changing the default roles in this list may enable unauthorized users to alter event integrations on the instance. To prevent unauthorized access to roles, set *evt_mgmt.connector_assignment_group_admin_roles* to the value of `admin,evt_mgmt_admin,sn_sow_srm.srm_admin`. Review any additional roles in the recommended value string to ensure that the role should be included.

More information

Attribute	Description
Configuration name	*evt_mgmt.connector_assignment_group_admin_roles*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	admin,evt_mgmt_admin,sn_sow_srm.srm_admin
Default value	admin,evt_mgmt_admin,sn_sow_srm.srm_admin
Fallback value	admin,evt_mgmt_admin,sn_sow_srm.srm_admin
Category	Access control

Attribute	Description
Security risk	• Severity score: 3.1 • CVSS rating: Low • Security risk details: Changing the default roles in this list may open up unauthorized users to altering event integrations on the instance.
Functional impact	Changing the default roles in this list may prevent previously authorized users from altering event integrations on the instance.
Dependencies and prerequisites	None

Configure service portal widgets allow list

Learn how to configure the glide.service_portal.widget.allow_list property securely so that the access control lists (ACLs) for the tables don't expose sensitive information.

The *glide.service_portal.widget.allow_list* system property determines the list of widgets that are allowed to attempt to access any table on the instance. ACLs for those tables will still be enforced. If there are misconfigured empty ACLs on tables on the instance, widgets in this list allow access to those tables, leading to information disclosure. This property is only enforced if the widget makes use of SNCACLWidgetUtil, and the property *glide.service_portal.widget.enforce_public_check* is set to '**true**.

Ensure that the *glide.service_portal.widget.allow_list* system property has an empty value empty or does not exist.

More information

Attribute	Description
Configuration name	*glide.service_portal.widget.allow_list*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	<empty>
Default value	''
Fallback value	<empty>
Category	Access control
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: Unauthenticated users may gain unintended access to sensitive table data via Service Portal widgets, resulting in potential information disclosure.
Dependencies and prerequisites	For the *glide.service_portal.widget.allow_list*

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	setting to be applicable, the *glide.service_portal.widget.enforce_public_check* property must be set to true.
Functional impact	This property enables customers to access any table information if the widget is set to public and is included in the property's value.

Configure service portal widgets table allow list

Learn how the *glide.service_portal.widget.table_allow_list* property enhances security by listing tables accessible to unauthenticated users through Service Portal widgets, dependent on additional checks and specific glide property settings.

The *glide.service_portal.widget.table_allow_list* property contains the list of tables allowed to be accessed by unauthenticated users through Service Portal widgets that make use of the additional security checks provided in the SNCACLWidgetUtil script include. This property is only enforced if the Glide Property The *glide.service_portal.widget.table_allow_list* property is **true**. There may be unauthenticated information disclosure if unnecessary tables are listed in this property. Table ACLs will still be evaluated as previously occurred.

Ensure that the *glide.service_portal.widget.table_allow_list* property is empty, or the list is restricted to the smallest number of tables with use cases for unauthenticated access.

More information

Attribute	Description
Configuration name	*glide.service_portal.widget.table_allow_list*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	<empty>
Default value	'' (empty string)
Fallback value	<empty>
Category	Access control
Security risk	• Severity score: 3.7 • CVSS rating: Low • Security risk details: Unauthenticated users may gain access to sensitive data through Service Portal widgets, potentially leading to information disclosure despite existing table ACLs.
Functional impact	The table list controls access to the tables from which the widget is allowed to retrieve data.
Dependencies and prerequisites	The *glide.service_portal.widget.enforce_public_check* property must be set to true for the

Attribute	Description
	glide.service_portal.widget.table_allow_list setting to take effect.

Configure unique MID Server users

Create a unique user account for each of your MID Servers to support auditability, enforce security controls, and enable least privilege access.

MID Server users authenticate MID Servers to the ServiceNow instance and enable communication to the instance. Configure each MID Server with a unique user account to support auditability and security controls. Assigning a unique user account to each MID Server follows the principle of least privilege and enables proper identity and access management for your service accounts.

Configure each MID Server with a unique user account that has been assigned the *mid_server* role:

1. Navigate to **All** > **User Administration** > **Users**.
2. Create a user for each MID Server (for example, `mid_server_prod_01`, `mid_server_dev_01`).
3. In the **Roles** section, assign the **mid_server** role to each user account.

   Note: Roles cannot be assigned until after the record is saved.

4. Configure each MID Server to authenticate with its dedicated user account.
5. Verify no duplicate **Logged in user** values exist in MID Server [ecc_agent] table records.

For existing shared user accounts:

1. Identify all MID Servers sharing the same user account. (Records in the MID Server [ecc_agent] table that have identical **Logged in user** field values).
2. Create unique user accounts (User [sys_user] records) for each MID Server.
3. Update each MID Server's configuration to use its dedicated account.
4. Test connectivity before decommissioning the shared account.

More information

Attribute	Description
Configuration name	User [sys_user] and MID Server [ecc_agent] table records.
Configuration type	User [sys_user] and MID Server [ecc_agent] table records.
Data type	Table record
Recommended value	Each MID Server [ecc_agent] record should have a unique User [sys_user] record in it's **Logged in user** field. This user should have the **mid_server** role.
Default value	N/A
Fallback value	N/A

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Access control
Security risk	• Severity score: 3.8 • CVSS rating: Low • Security risk details: When multiple MID Servers share the same user account, it is difficult to perform the following: ○ Determine which specific MID Server performed an action ○ Trace the source of suspicious or malicious activity ○ Implement granular access controls per MID Server ○ Investigate security incidents or operational issues ○ Comply with security logging and attribution requirements
Functional impact	Creating unique user accounts for each MID Server has no functional impact on MID Server capabilities or performance. All MID Servers will continue to operate normally with the **mid_server** role permissions.
Dependencies and prerequisites	None

CSRF enforcement for session-authenticated REST APIs

The *glide.security.csrf.rest.public_csrf.enabled* property enables Cross-Site Request Forgery (CSRF) token validation for public REST APIs that use session-cookie authentication.

A CSRF token is a unique, session-specific security token embedded in requests. The server validates that the token matches the one it issued, confirming the request's legitimacy and preventing attackers from performing unauthorized actions on behalf of users.

When the *glide.security.csrf.rest.public_csrf.enabled* property is set to `true`, all public REST APIs using session-cookie authentication must include a valid CSRF token in their requests. Requests without a valid token are rejected.

You can exempt specific REST API paths from CSRF validation by adding them to the sys_rest_csrf_allow_list table. Paths on this allowlist will not require CSRF tokens.

When the *glide.security.csrf.rest.public_csrf.enabled* property is set to `false`, CSRF token validation is turned off entirely.

More information

Attribute	Description
Configuration name	*glide.security.csrf.rest.public_csrf.enabled*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Security risk	• Security rating: Medium • CVSS score: 4.3 • Security risk details: Setting this property to `false` disables CSRF token validation for public REST APIs, exposing them to potential CSRF attacks when using session cookies for authentication. A CSRF attack is an attack that forces an end user to execute unwanted actions on a web application in which they are currently authenticated. Typically enabled by social engineering, an attacker may trick the users of a web application into executing actions of the attacker's choosing. If the victim is a normal user, a successful CSRF attack can force the user to perform state-changing requests like changing their email address. If the victim is an administrative account, CSRF can compromise the entire web application.
Dependencies and prerequisites	None
Functional impact	Setting this property to `true` may cause some customer instance scripts and integrations to break. However, this is only if these scripts and integrations rely on session cookie authentication and make requests to public REST API endpoints without including a valid CSRF token. Integrations that use supported authentication methods (such as OAuth or basic auth) or correctly include the CSRF token will continue to work without changes.

Deny internal access to explicit external roles [Updated in Security Center 1.3 and 1.5]

Use system properties to determine whether external users can be assigned the snc_internal role.

Use the *glide.security.explicit_roles.enable_internal_user_blacklist* system property to prevent external users from being assigned the *snc_internal* role. When this property is set to **true**, it enforces the parameters of the maint-protected *glide.security.explicit_roles.internal_user_blacklist* property. This property assigns the *snc_external* role to a list of untrusted user classes. If *glide.security.explicit_roles.enable_internal_user_blacklist* is set to **false**, the *glide.security.explicit_roles.internal_user_blacklist* property is ignored.

Note: Instances without Explicit Roles installed are not affected. As of the Paris release, new installations of Explicit Roles get the property with a default value of true.

More information

Attribute	Description
Configuration name	*glide.security.explicit_roles.enable_internal_user*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Session management
Security risk	• Severity score: 5.4 • CVSS score: Medium • Misconfiguration of this property increases the risk that an external user account gains access to internal information.
Dependencies and prerequisites	None

Deny unauthorized access to request items

The *glide.sc.req_for.roles.default* property defines a default behavior for the *retrieveAddress* API.

The *glide.sc.req_for.roles.default* system property defines a default behavior for the *retrieveAddress* API. When there are no roles given in the *glide.sc.req_for.roles* property, the client callable script include *ScriptServiceCatalogGetLocation* can be called by any unprivileged logged-in user and can retrieve the address of any other users in the system.

Ensure that the property *glide.sc.req_for.roles.default* is set to `deny`.

More information

Attribute	Description
Configuration name	*glide.sc.req_for.roles.default*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	deny
Default value	deny
Fallback value	deny
Category	Access control
Security risk	• Severity score: 4.2 • CVSS rating: Medium

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Security risk details: If *glide.sc.req_for.roles.default* is not set to the recommended value of deny and the value of *glide.sc.req_for.roles* is empty, then any user can request items for other users allowing unauthorized resource access.
Functional impact	None
Dependencies and prerequisites	None

Display recommendations for high risk UI pages

Decrease the likelihood of authorization errors, and unintended information disclosure by displaying recommendations for high risk UI pages.

Use the **glide.script.ui_page.customer_scoped.security_msgs_enabled** system property to determine whether to display security recommendations to users configuring UI pages when:

- An ACL is missing
- GlideRecord/GlideDBQuery APIs are used instead of GlideRecordSecure
- the page is configured as public in the "sys_public" table

When the property is enabled, recommendations when the preceding conditions are met, decreasing the likelihood of authorization errors, and helping prevent unintended information disclosure.

Set the system property **glide.script.ui_page.customer_scoped.security_msgs_enabled** to **true** to display these recommendations.

More information

Attribute	Description
Technical configuration name	glide.script.ui_page.customer_scoped.security_msgs_enabled
Plugin applicability	None
Security risk	Setting this system property to **false** increase the likelihood of authorization errors, and unintended information disclosure.
Common Vulnerability Scoring System (CVSS) score	5.3
Common Vulnerability Scoring System (CVSS) rating	Medium
Functional impact	Displays security recommendations to users configuring UI pages.
Dependencies and prerequisites	None
Data type	Boolean

Fallback value	true
Recommended value	true

To learn more about adding or creating a system property, see Add a system property.

Disable adding default roles to skill ACLs

Use system properties to control what roles are automatically added to generative AI skill ACLs.

Use the *com.glide.one_extend.include_default_roles_for_skill_acl* system property to control whether roles are automatically added to generative AI skill ACLs when they're created or updated using the global.GenAiSkillSecurityUtils API. This property is used to enforce consistent security policies across all AI skills.

When a skill ACL is inserted or updated, the default roles defined in the *com.glide.one_extend.default_roles_for_skill_acl* system property are automatically included. This addition ensures that certain privileged roles always have access to execute the skills. The *com.glide.one_extend.default_roles_for_skill_acl* property may contain a comma-separated list of roles.

Roles are automatically added to Generative AI Skill ACLs when *com.glide.one_extend.include_default_roles_for_skill_acl* is set to true. Depending on the role, this may allow overly broad access to certain skills and override intended ACL behavior.

1. Navigate to /sys_properties_list.do on the instance.
2. Ensure the *com.glide.one_extend.include_default_roles_for_skill_acl* property does not exist in the sys_properties table or is set to `false`.

More information

Attribute	Description
Configuration name	*com.glide.one_extend.include_default_roles_*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Access control
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: Roles are automatically added to Generative AI Skill ACLs when *com.glide.one_extend.include_default_roles*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	is set to true. Depending on the role, this may allow overly broad access to certain skills and override intended ACL behavior.
Functional impact	When *com.glide.one_extend.include_default_roles_* is set to `false`, roles are no longer automatically granted access to generative AI skill ACLs — any role that needs to execute a skill must satisfy the skill's own access control instead of relying on an automatically-added default role. The related *com.glide.one_extend.default_roles_for_skil* property, which lists which roles get auto-added when *com.glide.one_extend.include_default_roles_* is set to true, has no effect while it is set to false.
Dependencies and prerequisites	None

Disable inbound emails for locked out users

Use the *glide.pop3.process_locked_out* property to control inbound email actions for locked out, active users.

The *glide.pop3.process_locked_out* system property controls inbound email actions for locked out users. If *glide.pop3.process_locked_out* is set to **true**, there may be an information disclosure as inbound emails would be received by users with locked accounts.

Ensure that the property *glide.pop3.process_locked_out* is set to **false**.

Note: Consider the security implications of allowing users from untrusted domains, and why they were locked out, before allowing emails from them to trigger inbound email actions.

More information

Attribute	Description
Configuration name	*glide.pop3.process_locked_out*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Access control
Security risk	• Severity score: 7.5 • CVSS rating: High

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Security risk details: Allows locked-out users to continue submitting inbound emails that may create records or trigger workflows, posing a security risk by enabling potentially unauthorized actions.
Functional impact	None
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Disable log-and-allow mode for cross-scope dot-walk access

The *glide.script.dot_walk.log_and_allow_violations* property controls logging and enforcement of access violations when dot-walk is used cross-scope.

This property determines whether access violations are logged when dot-walk is used to access table data cross-scope. When enabled, this property logs violations without preventing cross-scope table access through dot-walk.

When set to `true`, access violations are logged but not enforced. When set to `false`, logging is turned off and enforcement is controlled by the *glide.script.dot_walk.enforce_cross_scope_access_all_tables* property.

To configure this property:

1. Navigate to `/sys_properties_list.do` on the instance.
2. Confirm the *glide.script.dot_walk.log_and_allow_violations* property doesn't exist in the sys_properties table or is set to `false`.

More information

Attribute	Description
Configuration name	*glide.script.dot_walk.log_and_allow_violations*
Configuration type	System Properties (/sys_properties_list.do)
Data type	true | false
Recommended value	false
Default value	false
Fallback value	false
Category	Access control
Security risk	• Severity score: 6.4 • CVSS rating: Medium • Security risk details: When this property is set to `true`, authorization checks aren't performed for dot-walk occurring cross-scope. Without authorization

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	checks, dot-walk can be used by an application to access tables that are outside the application scope, potentially exposing sensitive data.
Dependencies and prerequisites	When set to `true`, this property supersedes the *glide.script.dot_walk.enforce_cross_scope_access_a* property. No enforcement of access control for cross-scope dot-walk occurs, regardless of the other property value. When set to `false`, enforcement for cross-scope access control when using dot-walk is controlled by the *glide.script.dot_walk.enforce_cross_scope_access_a* property.
Functional impact	When set to `true`, this property logs access violations, but does not enforce access control for cross-scope dot-walk, similar to the behavior of prior releases. When set to `false`, logging is turned off, and enforcement is controlled by the *glide.script.dot_walk.enforce_cross_scope_access_a* property. There is no functional impact on application behavior when toggling this property.

Disable Voice Chat Guest Impersonation

Use a system property to ensure that voice interactions/conversations are recorded under the appropriate internal integration user.

When an inbound or outbound call triggers the Start Voice Interaction API in a domain-separated environment, interactions are created under the guest user and in the default domain. This causes failures when retrieving interaction records due to domain mismatches, as the interaction is inaccessible to the actual user. This happens because the API call impersonates the guest user despite being invoked by a logged-in user, leading to interactions created in sibling domains that restrict access.

When the property is set to false, voice interactions/conversations are recorded under the guest user. This is a generic user that doesn't accurately reflect the identity of the security principal creating the record.

When the property is set to true, voice interactions/conversations are recorded under the appropriate internal integration user.

Confirm that the *com.glide.cs.voice.chat.disable.guest.impersonate* system property is set to true in the System Properties [sys_properties] table, or that the property doesn't exist in the table.

More information

Attribute	Description
Configuration name	*com.glide.cs.voice.chat.disable.guest.impersonate*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Default value	true
Fallback value	true
Category	Access control
Security risk	• Severity score: 1.9 • CVSS score: Low • Security risk details: If an attacker is able to inject records as the guest user, then platform users would not be able to distinguish between valid and spoofed records, leading to longer troubleshooting efforts.
Functional impact	There is no impact on system functionality. The property affects the way the Now platform logs internal actions.
Dependencies and prerequisites	None

Double check inbound transactions

Use the *glide.security.strict.updates* property to enable double-checking of security on inbound transactions during form submission. When you set this property to **true**, it adds an extra layer of table validation before a form renders in the browser.

The *glide.security.strict.updates* system property provides an extra layer of security on form submission / field updates by ensuring only users with the proper permissions are allowed to update a form. If *glide.security.strict.updates* is not set to the recommended value of **true**, then updates are not strict meaning they are able to modify fields visible to them regardless of whether they have the appropriate permissions.

Ensure that the property *glide.security.strict.updates* exists in the System Properties [sys_properties] table and is set to "true".

⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.security.strict.updates*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Access control
Security risk	• Severity score: 8.1 • CVSS rating: High

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Security risk details: Users may be able to update form fields simply by having visibility into them, regardless of their actual permissions, creating a risk of unauthorized data modification and privilege escalation.
Functional impact	None
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Enable scoped admin application ACLs

The *glide.security.scoped_administration.honor_global_acl* determines whether an application administration app can inherit global access control list (ACL) rules.

The *glide.security.scoped_administration.honor_global_acl* system property determines whether an application administration apps can inherit global access control list (ACL) rules. Useful when there are no scoped admin application ACLs defined for the record scope.

Ensure that the property *glide.security.scoped_administration.honor_global_acl* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.security.scoped_administration.honor_global_*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	<none>
Fallback value	false
Category	Access control
Security risk	• Severity score: 3.8 • CVSS rating: Low • Security risk details: Low privilege users with permissions to the application could potentially access sensitive records.
Functional impact	None
Dependencies and prerequisites	None

To learn more about activating a plugin, see Activate a plugin

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Enable work order management query rules for service organizations

Use the *sn_fsm.use_query_rules* property to apply rules and filters to the Field Service Management tables.

When set to **true**, rules/filters from sn_query_rule table will be used to determine read access to Field Service Management-related tables (Work Order and Work Order Task) to the logged in user through query business rules and read ACLs. When **false**, the records won't be filtered based on query rules. Query business rules add additional security validations. Specifically, this property will filter records for agents, qualifiers, and dispatchers based on their assigned territory or territory membership. It is best practice to follow the principle of least privilege when reading records.

Set the *sn_fsm.use_query_rules* system property to **true**.

More information

Attribute	Description
Configuration name	*sn_fsm.use_query_rules*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Category	Access control
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: There may be increased risk of data exposure from Field Service Management tables.
Dependencies and prerequisites	None
Functional impact	When set to true, rules/filters from sn_query_rule table are used to determine read access to Field service management related tables. For example, Work Order (WO) and Work Order Table (WOT) to the logged-in user through query business rules and READ ACLs. When false, the records aren't filtered based on query rules. Enabling this property secures the data, and all data (wm_task and wm_order) won't be visible to their users.
References	

Enable ACLs to Control Live Profile Details

Use the *glide.live_profile.details* property to designate whether a user should be able to view all detail fields, such as company name and phone numbers, in a live profile.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Use the *glide.live_profile.details* system property to designate whether a user should be able to view all detail fields, such as company name and phone numbers, in a live profile under the live feed feature.

If *glide.live_profile.details* is set to the value of `hide`, then no live profile information is visible to user. If it is set to `show`, all information is visible. When *glide.live_profile.details* is set to the value of `ACL`, information is visible based on the user's profile ACLs.

Ensure the property *glide.live_profile.details* is set to `ACL`.

More information

Attribute	Description
Configuration name	*glide.live_profile.details*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	ACL
Default value	ACL
Fallback value	ACL
Category	Access control
Security risk	• Severity score: 4.3 • CVSS rating: Medium • Security risk details: Exposing sensitive user information such as company affiliation and contact details to unauthorized users increases the risk of data leakage and violating privacy controls if ACLs are not enforced.
Functional impact	None
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Enable ACLs for Encoded Query in Simple List Widget

Learn how to set the *glide.service_portal.enable_acls_for_encoded_query_in_list* property to the secure value to prevent users from bypassing access control list (ACL) evaluations on a query condition in the Simple List Widget.

When the *glide.service_portal.enable_acls_for_encoded_query_in_list* system property is not set to **true**, a user may be able to bypass ACLs evaluation on a query condition in Simple List Widget.

Ensure that the glide property *glide.service_portal.enable_acls_for_encoded_query_in_list* is set to **true**. If the property does not exist in the System Properties [sys_properties] table, the default value is **true**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*com.glide.script.fencing.cross_scope_access.shared*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	true
Default value	true
Fallback value	
Category	Access control
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: It is general guideline to evaluate ACLs within queries to confirm a user has access to the fields being queried to prevent unauthorized data leakage.
Dependencies and prerequisites	None
Functional impact	The Simple List Widget may not display any data depending on the user's role and the underlying ACLs. Additionally, users might encounter security warnings if the Simple List query contains filter conditions with properties that aren't accessible to the current user.

Enable Guardian for External Agents

Use a system property to protect your Language Learning Models (LLMs) with Guardian.

Use the *sn_aia.external_agent_guardian_check* system property to enable Guardian, which monitors requests sent to Language Learning Models (LLMs) and their responses to help protect you, your users, and your data. There are three types of content that are monitored for:

- offensive or harmful content
- prompt injection attempts
- filtered subjects

Ensure that the *sn_aia.external_agent_guardian_check* system property does not exist in the System Properties [sys_properties] table, or exists and is set to a value of `true`.

More information

Attribute	Description
Configuration name	*sn_aia.external_agent_guardian_check*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Access control
Security risk	• Severity score:4.1 • CVSS score: Medium • Security risk details: Prompt injection is a type of attack where bad actors override the normal instructions of an LLM to access restricted information or elicit unexpected behaviors. Prompt injection detection is based on the LLM which has been trained on various types of prompt injection techniques such as role playing, paraphrasing, repetition, instructions to ignore other instructions, persuasion, etc.
Functional Impact	Guardian may produce false positives and block legitimate requests.
Dependencies and prerequisites	None

Enable anti-CSRF token

Use the *glide.security.use_csrf_token* property to confirm the use of a secure token to identify and validates incoming requests, which in turn are used to prevent these attacks.

Cross-Site Request Forgery (CSRF) is an attack that forces authenticated users to submit a request to a web application, exploiting the web application's trust in an authenticated user.

The *glide.security.use_csrf_token* property controls whether the platform embeds a token in rendered pages and validates that token on incoming requests. This allows the platform to distinguish requests that originated from its own pages from requests forged by a third-party site.

To configure this property:

1. Confirm the current user has the security_admin role or has elevated to that role.
2. Navigate to /sys_properties_list.do on the instance.
3. Confirm the *glide.security.use_csrf_token* property exists and is set to `true`.

More information

Attribute	Description
Property name	*glide.security.use_csrf_token*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Purpose	To protect the application from potential CSRF attack.
Fallback value	false
Recommended value	true
Default value	true
Functional impact	Requests with a missing, expired, or mismatched token are rejected and the user is redirected to a security warning page instead of having the action performed.
Security risk	• Security risk rating: High • CVSS rating: 8.1 • Security risk details: If this property is not set to `true`, the platform can't distinguish a forged request from one the user actually intended. An attacker can craft a malicious page that causes an authenticated victim's browser to submit a request to the instance without their knowledge. That request executes with the victim's session and privileges.

To learn more about adding or creating a system property, see Add a system property.

Enable contextual security plugin

Activate the Contextual Security Plugin (*com.glide.role_management*) plugin to enable contextual security, which secures a record/information using create, read, write, and delete functionality.

The Contextual Security Plugin (*com.glide.role_management*) plugin helps manage user groups and roles to protect information through role-based access controls. The plugin efficiently consolidates duplicate entries for inherited roles, and secures a record/information using create, read, write, and delete functionality. After it is installed and activated, the dictionary roles (created by security manager) are no longer tested. Instead, the Now Platform looks for ACL rules on fields and tables. It secures the data with the help of ACL rules instead of traditional, role-based dictionary rules implemented by simple security manager. Even if you configure the dictionary form and add roles to a dictionary entry, no change in rights occurs.

Ensure that the plugin *com.glide.role_management* is activated.

More information

Attribute	Description
Configuration name	*com.glide.role_management*
Configuration type	System Definition > Plugins
Data type	N/A
Recommended value	The Contextual Security Plugin (*com.glide.role_management*) plugin is active.
Default value	The Contextual Security Plugin (*com.glide.role_management*) plugin is not active by default.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Fallback value	The Contextual Security Plugin (*com.glide.role_management*) plugin is not active by default.
Category	Access control
Security risk	• Severity score: 8.1 • CVSS rating: High • Security risk details: Failing to transition fully to ACL-based controls may leave sensitive data exposed due to overlooked or outdated dictionary role configurations.
Functional impact	This remediation enforces functional level of access controls, which would let application determine the access restrictions based on ACL table alone.
Dependencies and prerequisites	None

Enable Cross Scope Privilege Checks on Service Portal Form [New in Security Center 7.0]

Use a system property to enforce cross scope privilege checks on the Service Portal form widget and prevent unauthorized retrieval of forms and table data between scopes.

In Yokohama and later releases, queries enforce cross scope privilege checks on the table before reading the given sys_id information.

When the *glide.service_portal.enforce_cross_scope_check_in_form* property is set to the recommended value of **true**, cross scope privilege checks are enforced on the table. When set to **false**, the cross-scope privilege check isn't enforced.

Set the *glide.service_portal.enforce_cross_scope_check_in_form* system property to **true** or confirm that the property doesn't exist in the System Properties [sys_properties] table. If a record doesn't exist in the sys_properties table, the value defaults to **true**.

More information

Attribute	Description
Configuration name	*glide.service_portal.enforce_cross_scope_check_in*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control

Attribute	Description
Security risk	• Severity score: 3.1 • CVSS score: Low • Security risk details: A lack of cross scope privilege checks could lead to unauthorized retrieval of forms and table data between scopes.
Dependencies and prerequisites	None

Enable CSRF enforcement for authenticated processors

Enable Cross-Site Request Forgery (CSRF) enforcement to protect authenticated processor requests from CSRF attacks when session cookies are used for authentication.

The *glide.security.csrf.processor.all.authenticated.enabled* property enables CSRF checks for authenticated processor requests. When set to `true`, the platform checks for CSRF violations after session cookie authentication succeeds. If a violation is detected and the processor is not allow-listed, the request is rejected with an HTTP 401 response. Rejection details are logged. This enforcement applies to POST, PUT, and DELETE requests. GET requests are allowed without a CSRF token.

The *glide.security.csrf.httpauth_processor_allowlist* property controls an exception list that allows specific processors extending HTTPAuthProcessor to bypass CSRF enforcement. When *glide.security.csrf.processor.all.authenticated.enabled* is active, requests to processors named in this allow-list bypass the HTTP 401 rejection for invalid or missing CSRF tokens.

Note: The *glide.security.csrf.processor.all.authenticated.enabled* property is a broader upstream gate that supersedes *glide.security.csrf.rest.public_csrf.enabled* for cookie-auth REST traffic when both are enabled. The *glide.security.csrf.rest.public_csrf.enabled* property is effectively the specific guard for public REST API pages that the *glide.security.csrf.processor.all.authenticated.enabled* property does not cover (for example, public REST requests sent with a session cookie where the page does not require cookie authentication).

More information

Attribute	Description
Configuration name	*glide.security.csrf.processor.all.authenticated.enabled*, glide.security.csrf.httpauth_processor_allowlist
Configuration type	System Properties (`/sys_properties_list.do`)
Data type	Boolean, String
Recommended value	glide.security.csrf.processor.all.authenticated.enabled: true glide.security.csrf.httpauth_processor_allowlist: ""

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Default value	glide.security.csrf.processor.all.authenticated.enabled: false glide.security.csrf.httpauth_processor_allowlist: ""
Fallback value	glide.security.csrf.processor.all.authenticated.enabled: false glide.security.csrf.httpauth_processor_allowlist: ""
Security risk	Setting the *glide.security.csrf.processor.all.authenticated.enabled* property to `false` disables CSRF token validation for authenticated processor requests, allowing CSRF attacks when session cookies are used for authentication. A CSRF attack tricks an authenticated user's browser into making requests to a web application on the attacker's behalf, without the user's knowledge. The browser automatically attaches session cookies to outbound requests. A malicious page can silently trigger state-changing actions (password changes, record updates, privilege escalations) on any site the victim is currently logged in. The impact scales with the victim's privileges. A regular user loses control of their own account. An administrator can expose the entire instance.
Functional impact	Changing the *glide.security.csrf.processor.all.authenticated.enabled* property directly affects whether requests that change state and are authenticated via session cookies to HTTPAuthProcessor-based endpoints must present a valid CSRF token. Enabling this property can cause previously working integrations, browser-driven calls, or custom clients to start receiving HTTP 401 responses. This occurs if they rely on session cookies but don't send a valid X-UserToken. Disabling it preserves backward compatibility for such clients but weakens CSRF protection.
Regression testing	Log in to establish a session and call an affected processor endpoint using POST, PUT, or DELETE in three ways: without a token, with an invalid token, and with a valid token. When the property is enabled, the requests without a token, and those with an invalid token are rejected. The requests with a valid token should succeed. Confirm GET requests continue to work without requiring a CSRF token.
Related property	*glide.security.csrf.httpauth_processor_allowlist*

Enable policy based session access for mobile

Use the The Zero Trust- Policy Based Session Access plugin to control if users authenticating through a mobile app will have their roles reduced.

The *Zero Trust - Policy Based Session Access* plugin allows security admins to reduce user access in a session based on IP, Location, Identity provider attributes and user

© 2026 ServiceNow, Inc. All rights reserved.

attributes using adaptive authentication policies. When this property is set to **true**, then users logging in via mobile device will have their roles restricted as configured by the plugin policies.

Set the Glide Property *glide.authenticate.session_access.mobile.enabled* to **true**.

More information

Attribute	Description
Configuration name	*glide.authenticate.session_access.mobile.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Access control
Security risk	• Severity score: 4.7 • CVSS rating: Medium • Security risk details: Instance admins may wish to restrict high privileged access when users login via mobile device, possible indicating an unsafe environment for sensitive operations.
Functional impact	None
Dependencies and prerequisites	None

Enable Role Masking for Agents

Use a system property to enable the role masking feature.

Use the *identity.agent.role_masking.enabled* system property to enable the role masking feature. Role masking limits the roles that an AI agent uses when executing tasks. This configuration helps to prevent unnecessary access to resources not needed within the context of an agent. When this property isn't set to `true`, agents automatically inherit all roles from the user invoking them, potentially increasing the risk of privilege escalation and accidental data exposure.

Ensure that the *identity.agent.role_masking.enabled* system property exists in the System Properties [sys_properties] table and is set to a value of `true`.

More information

Attribute	Description
Configuration name	*identity.agent.role_masking.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean

Attribute	Description
Recommended value	true
Default value	true
Fallback value	false
Category	Access control
Security risk	• Severity score: 5 • CVSS score: Medium • Security risk details: When this property isn't set to `true`, agents automatically inherit all roles from the user invoking them. It may increase the risk of privilege escalation and accidental data exposure.
Functional Impact	If misconfigured, restrictive role masking may block intended access to a resource.
Dependencies and prerequisites	None

Enable IAM and boundary checks for Amazon Bedrock access

Enable IAM and Boundary Checks for Amazon Bedrock access.

AWS permissions for Amazon Bedrock are set using Identity and Access Management (IAM) policies. For example, the `bedrock:InvokeModel` policy allows an application to call `InvokeModel` function on all available models in all AWS regions. Bedrock boundaries restrict the scope of permissions granted by IAM policies. For example, a boundary can limit the `bedrock:InvokeModel` permission to only the Haiku 3.5 model and specific regions.

The *`sn_ai_security.bedrock_priviledge.permission_policy`* system property determines whether an application checks both the IAM policy and the Bedrock boundary configuration to verify whether a role is allowed to perform a privileged operation.

When set to the recommended value of `false`, the application validates both checks. If it is set to `true`, then the application checks only on the IAM policy to decide whether a role is privileged.

Set the *`sn_ai_security.bedrock_priviledge.permission_policy`* system property to `false` or ensure that it doesn't exist in the sys_properties table to support defense in depth.

More information

Attribute	Description
Configuration name	*`sn_ai_security.bedrock_priviledge.permission_polic`*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false

Enforce ACL on HR lifecycle events data

Learn how to prevent unauthorized access to data in the Human Resources Lifecycle Events application by verifying that the *glide.enforce_security_scope.sn_hr_le property* is set to the secured value.

The *glide.enforce_security_scope.sn_hr_le* property limits the access control lists (ACLs) of several HR tables so that only the "sn_hr_le" scope is considered. If *glide.enforce_security_scope.sn_hr_le* isn't set to the recommended value of true, then the data from the Human Resources: Lifecycle Events application will be exposed to ACLs from all other scopes which could lead to unauthorized users accessing sensitive data. For example, an IT administrator gaining access to HR data.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.sn_hr_le*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Access control
Security risk	• Severity score: 6.5 • CVSS score: Medium • Security risk details: Not setting this property to the value of true, could cause the Human Resources: Lifecycle Events application data to be exposed to ACLs from all other scopes. This could lead to unauthorized users accessing sensitive data.
Dependencies and prerequisites	None

Enforce ACL on HR Core Data [New in Security Center 2.0]

Learn how to configure the *glide.enforce_security_scope.sn_hr_core* property so that the Human Resources Scoped App: Core (com.sn_hr_core) plugin does not expose sensitive data to access control lists (ACLs) from all other scopes.

The *glide.enforce_security_scope.sn_hr_core* property restricts the access control lists (ACLs) of several global data tables like sys_attachment and sys_email to only consider the sn_hr_core scope. If this property is not set to the recommended value of true, then data from the Human Resources Scoped App: Core plugin will be exposed to ACLs from all other scopes. For instance, this could result in the IT administrator gaining access to human resources data.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

Attribute	Description
	• Security risk details: Failing to set this property to the secure value true could expose data from the Human Resources: Virtual Agent Conversations scoped application to ACLs from all other scopes.
Dependencies and prerequisites	None

Enforce application specific ACLs only for application data

Avoid unauthorized or undesired access to application data by enforcing application-specific access control lists (ACLs) only for application data.

Enforce application-specific ACLs for application data residing in primary tables outside the application. When these properties have a value of **true**, only the application-specific ACLs are evaluated for access to the application data residing in these tables. Not all applications are designed to work in this configuration or use a System Property [sys_properties] record for this purpose.

These system properties use the **glide.enforce_security_scope.<scope>** naming format. For example, use the **glide.enforce_security_scope.sn_hr_sp** property for the Employee Center Core (sn_hr_sp) scope. The following application scopes contain this property:

- sn_doc
- sn_egd_act
- sn_egd_core
- sn_egd_goals
- sn_em
- sn_gsm
- sn_gsm_info_req
- sn_gsm_lic_prmt
- sn_gsm_lic_prmt_ex
- sn_gsm_soc_bnfts
- sn_hc_professional
- sn_hr_agent_ws
- sn_hr_ai_agents
- sn_hr_awa
- sn_hr_core
- sn_hr_ef
- sn_hr_er
- sn_hr_gen_ai
- sn_hr_hc
- sn_hr_le
- sn_hr_ra
- sn_hr_le_ent
- sn_hr_mii_base
- sn_hr_na_galileo
- sn_hr_pad
- sn_hr_pj
- sn_hr_sp
- sn_hr_va
- sn_hr_ws
- sn_imt_health_test
- sn_imt_tracing
- sn_imt_vaccine
- sn_ja
- sn_jny
- sn_lg_contracts
- sn_lg_matter
- sn_lg_ops
- sn_opp_market
- sn_professional
- sn_svc_appl_info
- sn_svc_appl_pgm_mg
- sn_talent_aia
- sn_uni_req
- sn_uni_task
- sn_egd_lh
- sn_ecn
- sn_ni_core
- sn_hr_voice_aia
- sn_tf
- sn_lco_cmn

For each application installed with the *glide.enforce_security_scope* property in the System Properties [sys_properties] table, (for example, *glide.enforce_security_scope.sn_hr_core*), verify the property value is set to **true**.

Dependencies and prerequisites	None

Enforce credential alias usage

Learn how to secure your credentials from unauthorized use by configuring the MID Server property.

The Management, Instrumentation, and Discovery (MID) Server is a Java application that runs as a Windows service or UNIX daemon on your local network. MID Server properties are listed in the [ecc_agent_property] table. You can access them in your instance by navigating to **MID Server** > **Properties**.

The MID Server property *alias_filtering_behavior* defines the behavior of Discovery aliases. When the behavior is not `strict`, then all credentials are used regardless of their aliases for Discovery schedules. This behavior might not be desirable in some circumstances, particularly for credentials with elevated privileges. Credential aliases provide more control over which credentials a Discovery schedule is allowed to use and helps prevent the unnecessary exposure of credentials with elevated privileges.

See MID Server properties for more details.

Important: This property has been deprecated and will be removed from future baselines.

Enforce cross-scope table access when performing dot-walk

The *glide.script.dot_walk.enforce_cross_scope_access_all_tables* property defines the base access control decision for all table data accessed through dot-walk when the access is cross-scope.

This property controls whether authorization checks are performed for all table data accesses that are cross-scope through dot-walk. When set to `true`, authorization checks are performed for all cross-scope table data accesses unless a table has explicitly set the *enforce_dot_walk_cross_scope_access* dictionary attribute to `false`.

When set to `false`, no authorization checks are performed for cross-scope table data accesses unless a table has explicitly set the *enforce_dot_walk_cross_scope_access* dictionary attribute to `true`.

To configure this property:

1. Navigate to `/sys_properties_list.do` on the instance.
2. Set the *glide.script.dot_walk.enforce_cross_scope_access_all_tables* property to `true`.

More information

Attribute	Description
Configuration name	*glide.script.dot_walk.enforce_cross_scope_access_a*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Access Control
Security risk	• Security risk rating: Medium • Security score: 6.4 • Security risk details: When this property is set to `false`, no authorization checks are performed for cross-scope table data accesses unless a table has explicitly set the *`enforce_dot_walk_cross_scope_access`* dictionary attribute to `true`. Without authorization checks, dot-walk can be used by an application to access tables that are outside the application scope, potentially exposing sensitive data.
Dependencies and prerequisites	When the *`glide.script.dot_walk.log_and_allow_violations`* property is set to `true`, it supersedes this property. No enforcement of access control for cross-scope dot-walk occurs, regardless of this property value. The enforcement for cross-scope access control when using dot-walk is controlled by this property when *`glide.script.dot_walk.log_and_allow_violations`* is set to `false`.
Functional impact	When set to `true`, authorization checks are performed for all cross-scope table data accesses unless a table has explicitly set the *`enforce_dot_walk_cross_scope_access`* dictionary attribute to `false`. Because dot-walk access control was not enforced cross-scope before the Zurich release, this may cause some applications to not function correctly if they attempt to access tables outside of their scope through dot-walk.

Enforce least privilege on scoped MCP OAuth tokens

The *`com.snc.platform.security.oauth.mcp.aig_scope_support`* property controls how OAuth access tokens are cached and reused for Model Context Protocol (MCP) flows in AI Gateway (AIG).

The MCP OAuth flows cache and reuse outbound access tokens issued on behalf of connected AIG clients. This optimization prevents the requirement to mint a new token for each repeated call to a downstream resource.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

When set to `true`, the cache key used to look up a reusable token is computed from the client's requested and baseline configured scopes. Requests carrying different scope combinations resolve to separate cached tokens instead of sharing one. When set to `false`, a single cached token is reused for every request from that client regardless of which scopes were involved when it was created.

To configure this property:

1. Navigate to `/sys_properties_list.do` on the ServiceNow instance.
2. Set the *`com.snc.platform.security.oauth.mcp.aig_scope_support`* property to `true`.

More information

Attribute	Description
Configuration name	*`com.snc.platform.security.oauth.mcp.aig_scope_support`*
Configuration type	System Properties (`/sys_properties_list.do`)
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	false
Category	Access control
Security risk	• Severity score: 4.3 • CVSS rating: Low • Security risk details: It is insecure to reuse a single cached access token across every request from a client, independent of which permissions were involved when that token was created. This approach allows a token issued under one context to be handed out again for an unrelated request. When the original context carried a broader set of permissions, a later, narrower request can still be served the same token. This blurs the boundary between what different requests are authorized to do creating a token confusion risk. A lower-trust or compromised request path can leverage access that was meant to be reachable through a different, more privileged context.
Functional impact	Enabling this control changes outbound-token issuance for MCP OAuth client-credentials and authorization-code flows. Instead of one shared token per user/client, the platform provisions or reuses a distinct outbound token per effective scope combination. This approach increases the number of stored token mappings for clients that vary their requested scopes across calls. Regression test MCP client credentials token issuance, the MCP authorization code flows, and outbound token reuse and expiry behavior for AIG connections.

Attribute	Description
Dependencies and prerequisites	None

Enforce field-level ACLs on records created from the filtered list view UI query string

Use a system property to prevent list filters from affecting the initial values of created records.

Use the *com.glide.acl_check_all_filter_on_new* system property to confirm field level ACLs are evaluated when query string parameters are applied during the creation of new table records triggered from the UI.

How filter query strings work:

When a new record is created from the list view UI, field values from the filter query string are applied to it.

For example, using this filter:

```
author={62826bf03710200044e0bfc8bcbe5df1}^state={3}
```

The **Author** field is assigned the value `62826bf03710200044e0bfc8bcbe5df1` and **State** is assigned the value 3, regardless of their default value.

The *com.glide.acl_check_all_filter_on_new* property verifies that field level ACLs are evaluated for all fields when a record is created from the filtered list view UI of a table.

However, exceptions are applied in the following order:

1. If the *ignore_filter_on_new* dictionary attribute is set for a field, the value of that field is never used during record creation from the filtered list view.
2. If the *acl_check_filter_on_new* dictionary attribute is set for a field, ACLs must be checked for that field during record creation from the filtered list view.
3. If the *allow_filter_on_new* dictionary attribute is set for a field, ACLs aren't checked for that field during record creation from the filtered list view.
4. The **sys_domain** field and other domain fields defined by the *glide.sys.domain.domain_determining_field.{table_name}* property aren't checked by ACLs on record creation from the filtered list view.
5. If the *com.glide.acl_check_all_filter_on_new* system property is set to `true`, ACLs must be checked for all other fields during record creation from the filtered list.
6. If a field's type is listed in the *com.glide.ignore_filter_on_new.field_types* system property, ACLs must be checked for that field on record creation from the filtered list view.

Confirm that the *com.glide.acl_check_all_filter_on_new* system property is set to `true`.

More information

Attribute	Description
Configuration name	*com.glide.acl_check_all_filter_on_new*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	false
Category	Access control
Security risk	• Severity score: 4.8 • CVSS score: Medium • Security risk details: When *com.glide.acl_check_all_filter_on_new* is set to `false`, then ACLs aren't checked for fields on new record creation from the filtered list view UI of a table, unless one of the other exceptions applies. In this state, users without create access to fields can bypass ACLs by setting protected fields through filter query strings during record creation. This allows protected fields to be set to improper values on record creation through the filtered list view UI of a table.
Functional impact	When *com.glide.acl_check_all_filter_on_new* is set to `true`, ACLs are enforced for fields included in the filter query string during record creation from the list view UI. This prevents users without create access from modifying protected fields through filter parameters.
Dependencies and prerequisites	None

Enforce Read Roles for Catalog Variable Search [New in Security Center 7.0]

Use system properties to ensure that only catalog variables with an empty read role are indexed for search.

When the property *glide.ais.ingestion.ignore_catalog_variables_read_roles* is set to the recommended value of **false**, only catalog variables with an empty read role are indexed for search. If this property is set to **true** then all variables are indexed for search regardless of any read roles specified on the variable.

Verify that the *glide.ais.ingestion.ignore_catalog_variables_read_roles* system property does not exist in the System Properties [sys_properties] table, or exists and is set to **false**.

More information

Attribute	Description
Configuration name	*glide.ais.ingestion.ignore_catalog_variables_read_*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.

Attribute	Description
Data type	Boolean
Recommended value	false
Default value	false
Category	Access control
Functional impact	This property affects the indexing of searchable content from catalog variables that require specific roles for read access.
Security risk	• Severity score: 2.6 • CVSS score: Low • Security risk details: Users will be able to search for variables that they do not have read roles to access to causing information disclosure.
Dependencies	None
References	Service catalog variables

Enforce security rules to sharing dashboards

Use the *glide.cms.dashboards.sharing_with_secure_search* property to control whether users can share dashboards.

When the *glide.cms.dashboards.sharing_with_secure_search* system property is not set to **true**, a user can share a dashboard to groups and roles that they don't personally have access to. This property enforces ACLs on searching the User [sys_user], Roles [sys_user_role], and Groups [sys_user_group] tables when sharing a dashboard.

Set the *glide.cms.dashboards.sharing_with_secure_search* system property is set to **true**.

More information

Attribute	Description
Configuration name	*glide.cms.dashboards.sharing_with_secure_search*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	false
Category	Access control
Security risk	• Severity score: 3.5 • CVSS score: Low

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Security risk details: Oversharing a dashboard may result in minor confidentiality impacts in cases where a user shares a dashboard with a user, group, or role that should not access to the dashboard.
Dependencies and prerequisites	None
References	Access control
Functional impact	This property applies security rules to the list of users, user groups, and roles that are visible when sharing dashboards.

Enforce scope security for public sector digital services [New in Security Center 1.3]

Use the *glide.enforce_security_scope.sn_gsm* property to control how the application data from the Public Sector Digital Services application is accessed.

The ServiceNow Public Sector Digital Services application lets you develop public sector applications that deliver digital services to constituents, businesses, and agencies.

When *glide.enforce_security_scope.sn_gsm* is set to false, access to the application data within the global tables of the Public Sector Digital Services app may be accessible based on the access control lists (ACLs) of those global tables. When this property is set to true, access to data residing in global tables are only evaluated based off the ACLs shipped directly in the Public Sector Digital Services app. Setting this property to false may lead to information disclosure from over permissive ACLs.

To remediate this security risk, set *glide.enforce_security_scope.sn_gsm* to true.

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.sn_gsm*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: Not setting this property to the recommended value could lead to information disclosure from over permissive ACLs.
Dependencies and prerequisites	None

Enforce scoped ACL access for information request playbooks [New in Security Center 1.3 and updated in 1.5]

Use the *glide.enforce_security_scope.sn_gsm_info_req* property to control access to playbook data for the Information Request playbooks feature.

The Information Request Administration application enables public sector end users to submit and track public record requests and provides government agents with a pre-defined process for handling and resolving these requests. If *glide.enforce_security_scope.sn_gsm_info_req* is not set to true, unexpected access could be granted to playbook data for the Information Request playbooks application. Set this property to true to only consider ACLs from the sn_gsm_info_req scope when granting access.

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.sn_gsm_info_req*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: If this property is set to false, then ACLs from all scopes are considered when granting access to playbook data in the scope master table. This would expose information request playbook data.
Dependencies and prerequisites	None
References	• Using Information Request Administration • Configure Information Requests service channel

Enforce strict deny for ACLs referencing only deleted or non-existent roles

Manage how the system handles access control lists that reference roles deleted from the system.

The *glide.security.acl_with_invalid_roles_strict_deny* property controls how the system handles access control lists (ACLs) that reference roles that have been deleted from the system. When enabled (the default), any ACL containing only non-existent role references is explicitly denied access and logged as an error, preventing potential unauthorized

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

access. When turned off, such misconfigured ACLs fall back to default logic that may grant access based on authentication state alone, potentially bypassing intended role-based restrictions.

This property protects against ACLs with deleted role references and executes on every record-level access check.

To configure this property:

1. Navigate to /sys_properties_list.do on the instance.
2. Ensure the *glide.security.acl_with_invalid_roles_strict_deny* property exists in the sys_properties table and is set to `true`.

More information

Attribute	Description
Configuration name	*glide.security.acl_with_invalid_roles_strict_deny*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Access control
Security risk	• Security risk rating: Medium • CVSS score: 5.1 • Security risk details: Disabling this property allows ACLs with deleted role references to fall back to default logic. Access is granted based on authentication alone, bypassing intended role requirements. Users without the originally-required role can access protected records after role deletion. This is particularly risky during role cleanup or application uninstalls that leave orphaned ACL references. This failure mode is silent and difficult to detect. It risks unauthorized data exposure or modification until misconfigured ACLs are manually remediated.
Functional impact	When enabled (the default), this property denies access to ACLs with all role references deleted and logs errors identifying affected rules for remediation. Partially invalid ACLs are unaffected. Only fully-orphaned role references trigger the denial, and the check incurs negligible performance overhead since invalid-role status is determined at ACL load time. Access is denied for ACLs with only deleted role references. Update

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	these rules with valid roles instead of relying on fallback behavior.
Dependencies and prerequisites	None

Enforce strict elevate privilege

Use the *glide.security.strict_elevate_privilege* property to control whether roles marked as privileged must be manually elevated for the user to be granted the role's capabilities.

When the *glide.security.strict_elevate_privilege* system property is set to **true**, roles marked as privileged must be manually elevated by an admin user when creating a new session. This grants the user the role's capabilities. When set to **false**, roles marked as privileged are automatically elevated during an admin user new session, and don't require manual elevation (with exception of security_admin). Setting this property to the secure value adds an extra layer of security validation to role elevation by privileged user.

Ensure that *glide.security.strict_elevate_privilege* is set to **true** as it allows a user with admin to manually elevate to a role they want.

More information

Attribute	Description
Configuration name	*glide.security.strict_elevate_privilege*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Access control
Security risk	• Severity score: 6.7 • CVSS score: Medium • Security risk details: This risks potential privilege misuse or accidental execution of high-impact actions. Requiring manual elevation adds a deliberate security checkpoint that helps prevent unauthorized or unintended access to sensitive capabilities.
Dependencies and prerequisites	None
Functional impact	This property strictly requires admin role users to elevate privileges when needed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Enforce security scope license and permit playbook [New in Security Center 1.5 and updated in 2.0]

Use this property to determine if only the access control lists (ACLs) within the License and Permit plugin will be used in determining access to the scope, or if ACLs from all scopes will be considered.

When the *glide.enforce_security_scope.sn_gsm_lic_prmt* property is set to the recommended value of true, then only ACLs within the License and Permit plugin are used to determine access to the scope. When this setting is configured to false, then License and Permit Playbooks data in scope master tables are exposed because ACLs from all scopes are granted access. To reduce data exposure, set *glide.enforce_security_scope.sn_gsm_lic_prmt* to the recommended value of true.

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.sn_gsm_lic_prmt*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 2.7 • CVSS score: Low • Security risk details: Configuring this setting to the recommended value of true secures the License and Permit Playbooks data in scope master tables by considering only ACLs from *sn_gsm_lic_prmt* scope for granting access. Setting this to false exposes the License and Permit Playbooks data in scope master tables by considering the ACLs from all scopes for granting access. For example, the IT Administrator can access License and Permit Playbooks data when this setting is false.
Dependencies and prerequisites	None
References	• Using License and Permit Playbook • Application scope

Enforce Security Scope for Agent Workspace for HR Case Management [New in Security Center 1.5 and updated in 2.0]

Configure the Agent Workspace for HR Case Management plugin so that data in scope master tables can only be accessed by users with the correct permissions, enforcing the principle of least privilege.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

When the *glide.enforce_security_scope.sn_hr_agent_ws* plugin is configured to the recommended value of true, then only the access control lists (ACLs) within the Agent Workspace for HR Case Management plugin are used to determine access to a resource. When this setting is set to false, then Agent Workspace for HR Case Management data in scope master tables are exposed because the ACLs from all scopes are granted access.For example, an IT Administrator can access Agent Workspace for HR Case Management data when this setting is set to false. To prevent this from happening, set *glide.enforce_security_scope.sn_hr_agent_ws* to the recommended value of true which ensures that the principle of least privilege exists as users can only access resources they have permission to.

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.sn_hr_agent_ws*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 2.7 • CVSS score: Low • Security risk details: Configuring this setting to false causes the Agent Workspace for HR Case Management data in scope master tables to be exposed because the ACLs from all scopes are granted access.
Dependencies and prerequisites	Agent Workspace for HR Case Management
Functional impact	Configuring this setting to true will enforce global ACLs to be executed for a table, if scoped ACLs do not exist for it.
References	• https://owasp.org/www-project-proactive-controls/#div-numbering • Add a component to Agent Workspace

Enforce Security Scope for Service Application Information [New in Security Center 2.0]

Use the *glide.enforce_security_scope.sn_svc_appl* property to ensure that the data in master scope tables is secured.

When the *glide.enforce_security_scope.sn_svc_appl_info* property is set to true, access to resources within the scope is determined solely by the access control lists (ACLs) from the Service Application Information plugin (sn_svc_appl_info). This ensures the security

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

of data in master scope tables by restricting access permissions to those defined within the sn_svc_appl_info scope.

If set to the insecure value of false, ACLs from all scopes are considered when granting access to data in master scope tables such as sys_attachment. This could lead to unauthorized access to sensitive information by users who do not have permissions for the Service Application Information data.

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.sn_svc_appl_info*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Access control
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: If this property is set to the insecure value of false, it can lead to unauthorized access to sensitive data by users who do not have permissions for the Service Application Information data.
Dependencies and prerequisites	The Service Applicant Information plugin (*com.sn_svc_appl_info*) must be activated for the *glide.enforce_security_scope.sn_svc_appl_info* property to be effective.

Enforce Scope Access Controls on New Tables

Use a system property to enforce cross-scope access checks for newly created tables.

The table dictionary attribute `enforce_dot_walk_cross_scope_access=true` enforces dot-walk cross-scope access enforcement for the applicable table. This enforcement applies to dot-walking across scope boundaries using a reference field to the applicable table. When the *glide.script.dot_walk.add_attribute_on_table_create* system property is not set to `false`, the attribute is added to the dictionary element of all new tables. This attribute is only added for new tables created after zBoot.

Ensure that the *glide.script.dot_walk.add_attribute_on_table_create* system property set to `true` in the System Properties [sys_properties] table.

More information

Attribute	Description
Configuration name	*glide.script.dot_walk.add_attribute_on_table_creat*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	null
Category	Access control
Security risk	• Severity score: 5.3 • CVSS score: Medium • Security risk details: An application can access data in tables outside of it's application scope, leading to information disclosure.
Functional impact	Cross-scope access checks are enforced by default for newly created tables. This prevents applications from accessing data outside their scope through a bypass. The behavior could be turned off on a table-by-table basis.
Dependencies and prerequisites	

Enforce field level ACLs in GlideRecordSandbox

Manage field level ACLs in GlideRecordSandbox on your instance.

Use the *glide.sandbox.fields.check_acl* property to enforce field level ACLs in GlideRecordSandbox. An example in which this property is applied is when a user can provide a script, like in *sysparm_query*. If this property is not set to the recommended value of **true**, ACL restrictions can be bypassed, which enables sensitive data to be compromised, such as a *sys_user.user_password* from an unauthorized user.

Warning: The value for this property is a no DB override. It can't be altered or overridden.

More information

Attribute	Description
Configuration name	*glide.sandbox.fields.check_acl*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 7.5 • CVSS score: High • Security risk details: Setting this property to **false** enables ACL restrictions to be bypassed which could expose sensitive data.
Dependencies and prerequisites	None

Enforce GroupBy ACLs

Configure your instance to conduct ACL checks on groupby columns.

Use the *glide.security.groupby_acl_check* system property to configure your instance to conduct ACL checks on groupby columns. If this property is set to the recommended value of **true**, then ACLs on groupby columns are honored by default. A table's *groupby_acl_check* attribute takes precedent over the *glide.security.groupby_acl_check* property. If the property is set to **false**, then ensure that any table which should have ACL checks on groupby columns has the *groupby_acl_check* attribute set to **true**.

Ensure the property *glide.security.groupby_acl_check* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.security.groupby_acl_check*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: Setting this property to **false** will disable ACLs check on groupby columns which could lead to information leakage.
Dependencies and prerequisites	None

Ensure archive table ACLs are checked

The *glide.security.enable_archive_table_acls* property controls whether access control lists (ACLs) of the original table, the table the archive table was created from, are evaluated to false.

The *glide.security.enable_archive_table_acls* system property controls whether ACLs added to archive tables are evaluated (**true**) or if only the ACLs of the original

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

table (the table the archive table was created from) are evaluated (**false**). There is no reason for this property to not be true since the original table ACLs will be evaluated regardless of its value and since a customer can simply avoid additional ACLs for an archive table by not adding them.

Ensure that the value of *glide.security.enable_archive_table_acls* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.security.enable_archive_table_acls*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Access control
Security risk	• Severity score: 3.0 • CVSS score: Low • Security risk details: If the property is set to false, ACLs added to archived tables will be ignored, an action which is counter intuitive and may lead to authorization bypass.
Functional impact	When this property is set to true, any active read ACLs on archive tables will be honored. If no active read ACLs exist or the property is set to false, the original table's (table from which data was archived) will apply to the archive table. **Note:** Only read ACLs are supported on archive tables. Other operations on archive tables are governed internally through an Access Handler.
Dependencies and prerequisites	None

Ensure dashboards creation/deletion requires access check [New in Security Center 1.3 and updated in 2.0]

The *glide.processors.check_access_before_process* system property enables access control list (ACL) enforcement for creating or deleting dashboards when a user is logged in.

Set the *glide.processors.check_access_before_process* system property to **true**. If the property does not appear in the System Properties [sys_properties] table, the fallback value is **true**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.processors.check_access_before_process*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Access control
Security risk	• Severity score: 6.3 • CVSS score: Medium • Security risk details: Disabling this property by setting it to false, enables an ACL bypass on dashboards. This allows all authenticated users with low privileges to delete and add dashboards.
Dependencies and prerequisites	None
Functional impact	This property controls the ability to create new sys_dashboards and delete existing dashboards when a user lacks the necessary access rights. When the value is set to false, users with inappropriate roles can add and delete sys_dashboard entries (though the GlideRecord layer should recheck the existing ACLs). A value of true restricts add and delete operations for users without the required access rights.

Ensure MID Server Users Have Appropriate Access Levels

Verify that your MID Server user accounts does not have more the necessary granted permissions.

Granting the MID Server user account admin-level privileges (such as admin, security_admin or discovery_admin) presents a significant security vulnerability that violates the principle of least privilege and dramatically expands the attack surface.

Administrators sometimes grant elevated permissions to quickly resolve connectivity issues or enable new integrations, then do not remove those permissions afterward. The result is a service account with far more access than necessary to perform its legitimate functions of facilitating communication between the ServiceNow instance and external systems within your network.

Review the User Roles [sys_user_has_role] table for MID Server users and confirm that the following roles are not assigned:

```
access_analyzer_admin, activity_admin, actsub_admin, admin,
 advisor_admin, agent_security_admin, ai_user_admin, aig_admin,

More information

Attribute	Description
Configuration name	sys_user_has_role.table, mid_server_user.role
Configuration type	User Roles (/sys_user_has_role.do)
Data type	User Roles [sys_user_has_role] record
Recommended value	mid_server, and additional custom roles that may vary based on customer integrations
Default value	mid_server
Fallback value	N/A
Category	Access control

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 5.7 • CVSS rating: Medium • Security risk details: Granting the MID Server user account admin-level privileges represents a significant security vulnerability that violates the principle of least privilege and dramatically expands the attack surface. The MID Server acts as a bridge between trusted internal networks and the ServiceNow instance, processing credentials, executing discovery probes, and handling sensitive configuration data. If a MID Server user account with excessive privileges is compromised, an attacker gains a powerful foothold with the ability to read, modify, or delete critical data across the entire ServiceNow instance. This could enable data exfiltration of sensitive CMDB information, manipulation of incident records, unauthorized access to customer data, or even privilege escalation to compromise additional systems.
Functional impact	MID Server is expected to run as intended without admin-level privileges.
Dependencies and prerequisites	None

Exclude Sensitive Tables and Fields from Data Generation [New in Security Center 7.0]

Use system properties to exclude tables and fields from Data Generation, which is used to generate fake data sets based on existing data. Tables and fields that are added to these exclusion lists can't be used for Data Generation feature.

Tables included in the *glide.data.generation.excluded.tables* system property are excluded from Data Generation in addition to metadata tables.

Fields included in a comma separated list for *glide.data.generation.excluded.fields.<TABLE-NAME>* are excluded from Data Generation in addition to any of these fields, if applicable:

- number
- roles
- sys_class_name
- sys_created_by
- sys_id
- sys_mod_count
- sys_tags
- sys_updated_by

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Review the list of tables included in the property *glide.data.generation.excluded.tables*. Add any tables which should be excluded from Data Generation to the comma separated list of tables. In addition, metadata tables will be ignored for data generation.

Review the list of fields for each table by looking at properties with the format: `glide.data.generation.excluded.fields.<TABLE-NAME>`. Add any sensitive fields for the specified table as a comma-separated list of values.

More information

Attribute	Description
Configuration name	• *glide.data.generation.excluded.tables* • *glide.data.generation.excluded.fields.**
Configuration type	System Properties (/sys_properties_list.do)
Data type	• Comma-separated list of table names • Comma-separated list of fields for a given table
Recommended value	• Comma-separated list of table names which should be excluded from Data Generation • Comma-separated list of field names which should be excluded from Data Generation for each applicable table
Default value	"",""
Category	Access control
Security risk	• Severity score: 2.6 • CVSS score: Low • Security risk details: Data in tables used in the Data Generation feature can have real or fake values populated as intended by the feature. Sensitive values in tables which should not be visible or replicated could be revealed to other instance users.
Dependencies and prerequisites	Data Generation plugin is in use

Prevent Users From Accepting Warning To Bypass CSRF Validation [Updated in Security Center 1.3 and 1.5]

Use the *glide.security.csrf.strict.validation.mode* property to enable CSRF token strict validation. If the CSRF token doesn't match, it prevents resubmission of the request.

This property prevents users from being able to accept a warning which allows a potentially malicious request to be sent to the instance. This warning appears when a POST request fails due to having a mis-matched anti-CSRF token belonging to one of the victim's other active sessions. If *glide.security.csrf.strict.validation.mode* is not set to the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

recommended value of true, then an attacker can formulate a CSRF attack utilizing a leaked anti-CSRF token from a different active session belonging to the victim. A POST request to an instance contains an anti-CSRF token within "sysparm_ck" or "X-UserToken" which matches the user's current session.

If the anti-CSRF token is instead tied to one of the user's other active sessions, the POST request will return a 302 redirection to security_interceptor.do with a Continue button available to the user when this property is set to false. Clicking this button will re-submit the request to the instance, except it will now having a valid anti-CSRF token. When this property is set to true, the 302 redirection to the security_interceptor.do page will not display a Continue button and the user will not be allowed to resubmit the request.A successful CSRF attack will allow an attacker to effectively perform any operation that the victim is able to perform.

More information

Attribute	Description
Property name	*glide.security.csrf.strict.validation.mode*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	To enforce strict validation of CSRF token, and prevents its reuse.
Data type	Boolean
Recommended value	true
Default value	true
Security risk rating	(Medium) Cross site Request Forgery is a significant security risk that violates the integrity of the instance data. An attacker can launch the CSRF attack on any instance user by abusing the trust of the instance user. With the help of social engineering attacks, a user can submit a malformed request to the instance on behalf of the attacker.
Security risk rating	3.7
Functional impact	This remediation enables an extra validation step before the instance user submits a write request to the instance. It checks whether the current CSRF token has been used previously. If Yes, it prevents submission of further write requests.
Security risk	(Medium) Cross site Request Forgery is a significant security risk that violates the integrity of the instance data. An attacker can launch the CSRF attack on any instance user by abusing the trust of the instance user. With the help of social engineering attacks, a user can submit a malformed request to the instance on behalf of the attacker.

Return to Configure and upload your customer supplied key to upload your wrapped key.

Restrict allowed domains for cross-origin iframe communication

Use a system property to enable cross-origin communication between iframes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Use the *glide.ui.concourse.onmessage_enforce_same_origin* property to prevent cross-origin communication from untrusted domains. If not set to the recommended value of `true` then validation is not performed for cross-origin messaging. If set to `true` then domains listed in the *glide.ui.concourse.onmessage_enforce_same_origin_whitelist* system property can propagate messages in the UI. Use *glide.ui.concourse.onmessage_enforce_same_origin_whitelist* to control which domains are allowed.

Ensure that the *glide.ui.concourse.onmessage_enforce_same_origin* property exists in the System Properties [sys_properties] table and is set to `true`.

More information

Attribute	Description
Configuration name	*glide.ui.concourse.onmessage_enforce_same_origin*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Access control
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: If a web page's event handlers don't perform proper origin validation, then another web page or script from any origin can communicate with it. These pages or scripts can also initiate any functionality performed by the event handler. This property allows potentially untrusted external domains to send messages to the ServiceNow instance, increasing the risk of cross-origin attacks like data theft or UI manipulation.
Functional impact	If you don't add intended domains to the inclusion list in the *glide.ui.concourse.onmessage_enforce_same_origin_w* system property, cross-origin messages from that domain aren't allowed.
Dependencies and prerequisites	None

Restrict delegated developers read access [Updated in Security Center 1.3]

If *com.glide.dd_allow_global_access_tables* does not contain the recommended value of wf_activity, wf_activity_definition, wf_workflow, wf_workflow_version, sp_portal, sp_widget, and sp_page, then those tables could be read by a delegated developer. This could provide the delegated developer read access to sensitive information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Property name	*com.glide.dd_allow_global_access_tables*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	wf_activity, wf_activity_definition, wf_workflow, wf_workflow_version, sp_portal, sp_widget, sp_page
Default value	wf_activity, wf_activity_definition, wf_workflow, wf_workflow_version, sp_portal, sp_widget, sp_page
Category	Access control
Security risk	• Severity score: 2.7 • CVSS score: Low • Security risk details: Ensure that *com.glide.dd_allow_global_access_tables* is set to wf_activity, wf_activity_definition, wf_workflow, wf_workflow_version, sp_portal, sp_widget, sp_page.

Require AJAXGlideRecord ACL checking

Use the *glide.script.secure.ajaxgliderecord* property to perform access control rule (ACL) validation when server-side records, such as tables, are accessed using GlideAjax APIs within a client script.

The *glide.script.secure.ajaxgliderecord* systm property toggles ACL validation for GlideAjax API calls. If *glide.script.secure.ajaxgliderecord* is not set to the recommended value of **true**, then ACL validation will not be completed for GlideAjax requests.

Ensure that the property *glide.script.secure.ajaxgliderecord* is set to **true**.

⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.script.secure.ajaxgliderecord*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Access control

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 8.1 • CVSS rating: High • Security risk details: This could lead to server-side resources being accessed by users without proper authorization.
Functional impact	This remediation enforces the ACL relationship with server-side records when the requests are made using the AJAXGlideRecord API calls. If the ACL configuration is not properly configured, then there is potential impact. For more details on its impact, and how to identify it, see Refer to Audit and review client-side GlideRecord (AJAXGlideRecord) transactions [KB0550828].
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Restrict write access on system fields to admin users [New in Security Center 7.0]

Use the *glide.rest.table_api.admin_only_sys_fields* system property to control write access the fields generated by the system.

The *glide.rest.table_api.admin_only_sys_fields* property controls write access to these fields:

- sys_id
- sys_created_by
- sys_created_on
- sys_updated_by
- sys_updated_on

When this property is set to **true**, only an admin can write to these fields that are system-generated values. When the property is set to **false** or it doesn't exist in the System Properties [sys_properties] table, users who have create or write access to a table can write to these system values using the Table API.

Set the property *glide.rest.table_api.admin_only_sys_fields* to **true** to prevent non-admin users from updating system fields on records.

More information

Attribute	Description
Configuration name	*glide.rest.table_api.admin_only_sys_fields*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Default value	false
Fallback value	false
Category	Access control
Security risk	• Severity score: 2.7 • CVSS score: Low • Users without the admin role could update fields such as sys_created_by or sys_updated_on. This access can impact the integrity of the created or updated record metadata, making records appear as if they were created by another user or updated at a different time.
Functional impact	Any integrations or users without the admin role that use the Table API to create or update records and change these fields are impacted. These requests to the Table API set the query parameter *sysparm_suppress_auto_sys_field* to **false** and set those fields in the request body.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Require Multi-Factor Authentication for AI Voice Agent

Use a system property to control whether Multi-Factor Authentication (MFA) is required for the AI voice agent authentication feature.

Use the *glide.voice.authenticate.mfa_mandatory* system property to control whether Multi-Factor Authentication (MFA) is required for the AI voice agent authentication feature. MFA requires users to provide two or more different verification factors to access a service or account. Examples of factors are SoftPIN or time-based one-time password (TOTP). More information about authentication factors for AI voice agents can be found at Explore authentication factors for AI voice agents.

Ensure the *glide.voice.authenticate.mfa_mandatory* system property is set to `true`.

Important: The sys_id of this System Properties [sys_properties] record should be e0f4e8bd70103210f87732f6ceab0a2f.

More information

Attribute	Description
Configuration name	*glide.voice.authenticate.mfa_mandatory*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Default value	true
Fallback value	true
Category	Access control
Security risk	• Severity score: 3.3 • CVSS score: Low • Security risk details: Enforcing MFA reduces the risk of account compromise if a single factor is leaked or compromised.
Functional impact	Users must configure multiple factors of authentication to use voice authentication. This is the default behavior.
Dependencies and prerequisites	AI voice agent authentication feature is set up and enabled.

Require approval for agent-based Office 365 group membership changes [New in Security Center 7.0]

Enable the approval flow for adding or removing Office 365 group members through the Microsoft 365 group membership AI Agent using a system property.

Use the *sn_itsm_aia.office_365_group_member_approval.required* system property to control whether the approval flow for adding or removing Office 365 group members through the AI agent is on or off. When the approval workflow is enabled, an approval record must be set to approved by a member of the group specified in the *sn_itsm_aia.office_365_group_member_approval.group_id* system property. If the *sn_itsm_aia.office_365_group_member_approval.group_id* property isn't configured, the *Microsoft 365 group member approvers* group is used.

More information

Attribute	Description
Configuration name	*sn_itsm_aia.office_365_group_member_approval.requi*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Access control
Security risk	• Severity score: 4.9 • CVSS score: Medium • Any user who can access the Microsoft 365 group membership AI Agent can and add and remove Office 365 group members from the Azure AD group if explicit approval from the specified approvers

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	group isn't required. Ensure that these changes are approved to reduce the risk of elevation of privilege by adding/removing members without proper authorization.
Functional impact	When *sn_itsm_aia.office_365_group_member_approval.requi* is set to **true**, a member of the group specified in *sn_itsm_aia.office_365_group_member_approval.<grou* must approve the Incident requesting addition or removal of Office 365 group members. If *sn_itsm_aia.office_365_group_member_approval.requi* is set to **false** then no approval is required and the AI Agent can autonomously handle the process of adding or removing members from an Office 365 group.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Prevent impersonating user from viewing application data

Use system properties to prevent an impersonating user from viewing application data.

Prevent admin level from accessing the application specific data belonging to that user when impersonating an account. This permission can be set at the application level by creating a system property specific to the application.

These system properties use the *<scope>.impersonateCheck* naming format (for example *sn_hr_core.impersonateCheck*). Create a system property with a value of **true** to prevent users from accessing the application-specific data belonging to another user when impersonating an account.

Note: Not all applications are designed to work in this configuration or have a System Properties [sys_properties] record for this purpose. The following scopes are configured to work with this property.

- sn_opp_market
- sn_jny
- sn_imt_vaccine
- sn_imt_health_test
- sn_hr_core
- sn_egd_goals
- sn_egd_core
- sn_egd_act
- sn_em
- sn_talent_aia
- sn_ecn

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

For each application with the *<scope>.impersonateCheck* property in the System Properties [sys_properties] table, ensure the property value is set to **true**.

Note: These properties can only be modified by the scoped administrator for the specific application.

Use this script to identify properties that require updates or creation on the instance:

```
var properties = [
        'sn_opp_market.impersonateCheck',
        'sn_jny.impersonateCheck',
        'sn_imt_vaccine.impersonateCheck',
        'sn_imt_health_test.impersonateCheck',
        'sn_hr_core.impersonateCheck',
        'sn_egd_goals.impersonateCheck',
        'sn_egd_core.impersonateCheck',
        'sn_egd_act.impersonateCheck',
 'sn_em.impersonateCheck',
 'sn_talent_aia.impersonateCheck',
        'sn_ecn.impersonateCheck'
    ];

    var pm = new GlidePluginManager();

    for (var i = 0; i < properties.length; i++) {
        var property = properties[i];
        var application = property.split('.')[0];
        var propertyValue = gs.getProperty(property, 'false');

        if (pm.isActive(application) &&
 propertyValue.toLowerCase() != 'true') {
            gs.print(property);
        }
    }
```

More information

Attribute	Description
Configuration name	*<scope>.impersonateCheck*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Access control
Security risk	• Severity score: 3.8 • CVSS score: Low • A value of **false** for these properties allows an admin level user to impersonate another user and access

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	application data with the impersonated user's access. This may be undesirable or allow for unauthorized data access in specific application contexts.
Functional impact	Admin level users aren't be able to impersonate another user and view that user's data in a specific application context.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Enforce oauth state parameter validation

Configure the *glide.oauth.state.parameter.required* property to prevent your instance from cross-site request forgery (CSRF) attacks.

The *glide.oauth.state.parameter.required* system property enables the **State** parameter to be required in an OAuth request for authorization code flow. Beginning in the Madrid release, the system property *glide.oauth.state.parameter.required* adds a **State** parameter for an OAuth request. For zbooted instances, the property is **true**. For upgraded instances, the property is not present, so the **State** parameter is not enabled. The **State** parameter is a string value, and should not contain special characters. The State parameter cannot be empty or " ". Not setting the **State** parameter to **true** ensures that an attacker cannot perform CSRF attacks during authentication can allow an attacker to perform operations as the victim.

Ensure that the property *glide.oauth.state.parameter.required* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.oauth.state.parameter.required*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Access control
Security risk	• Severity score: 4.2 • CVSS rating: Medium • Security risk details: Not enabling the *glide.oauth.state.parameter.required* property in OAuth authorization code flow increases the risk of Cross-Site Request Forgery (CSRF) attacks, potentially allowing attackers to impersonate users and perform unauthorized actions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	None
Dependencies and prerequisites	None

Enforce strict user image upload

Use the *glide.security.strict.user_image_upload* property to enable access control for the upload/update of a profile picture when performed on a user record.

If the *glide.security.strict.user_image_upload* system property isn't set to **true**, the hostname and certificate chain presented by remote hosts during a TLS connection initiated from the ServiceNow ServiceNow instance aren't validated.

This vulnerability compromises the security of the TLS connection and allows person-in-the-middle attacks, where communications between two parties are intercepted. This may lead to sensitive data disclosure.

To configure this property:

1. Navigate to `/sys_properties_list.do` on the instance.
2. Ensure the *com.glide.communications.httpclient.verify_hostname* property exists and is set to `true`.

More information

Attribute	Description
Configuration name	*glide.security.strict.user_image_upload*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Access control
Security risk	• Severity score: 3.7 • CVSS rating: Low • Security risk details: This vulnerability compromises the security of the TLS connection and allows person-in-the-middle attacks, where communications between two parties are intercepted. This may lead to sensitive data disclosure.
Functional impact	When the *com.glide.communications.httpclient.verify_hostnam* property is set to `true`, an outbound HTTPS connection is rejected if the remote host's certificate does not match the requested hostname or its certificate chain can't be validated. Outbound integrations to hosts with

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	a mismatched or misconfigured certificate will fail to connect once this property is set to true.
Dependencies and prerequisites	The *com.glide.communications.httpclient.verify_hostnam* property governs hostname and certificate chain validation independently of the *com.glide.communications.httpclient.verify_revoked* property, the overall gate for certificate revocation checking.

Restrict email domains for external user registration

Use the *sn_ext_usr_reg.allowed_email_domains* property to list acceptable external email domains.

The **sn_ext_usr_reg.allowed_email_domains** system property defines which email addresses are allowed to self-register to a ServiceNow instance. The format should be a comma separated list of acceptable email domains such as `domain1.com,domain2.com` where emails such as `example@domain2.com` will be accepted. If **sn_ext_usr_reg.allowed_email_domains** is not set with a list of acceptable domains, then users with any email address are allowed to register accounts on the instances. If not defined, malicious actors could perform registration using emails addresses from unwanted domains to gain authenticated access to the instance.

More information

Attribute	Description
Property name	*sn_ext_usr_reg.allowed_email_domains*
Configuration type	System Properties (/sys_properties_list.do), Communities Properties
Category	Access control
Purpose	List email domains to allow user email for registration.
Recommended value	Enter a list of domains in a comma-separated format, for example `domain1.com, domain2.com, domain3.com`. This format works with or without spaces between elements.
Configuration type	String
Security risk	(High) Malicious actors could perform registration using emails addresses from unwanted domains. Ensure that **sn_ext_usr_reg.allowed_email_domains** is not set to an empty value.
Functional impact	Email addresses from domains that aren't included in the comma separated list defined in the property aren't allowed to self-register to a ServiceNow instance.
Security risk rating	7.5
References	Communities

To learn more about adding or creating a system property, see Add a system property.

Enable High Security plugin

When you activate the High Security plugin, it creates or updates hundreds of different configurations to control the level of security on your instance. These configurations mitigate many of the top OWASP attacks by enabling strict access control, input validation, and output encoding.

The High Security plugin, activated by default, creates more than 900 different configurations to control the level of security on your instance. These configurations enable strict access control, input validation, and output encoding. It separates user functionality from access control management functionality through requiring administrators to explicitly elevate into a *security_admin* role before making access control changes.

Ensure that the plugin *com.glide.high_security* is activated.

More information

Attribute	Description
Configuration name	*com.glide.high_security*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Plugin
Recommended value	The plugin *com.glide.high_security* is active
Default value	
Fallback value	
Category	
Security risk	• Severity score: 9.8 • CVSS rating: Critical • Security risk details: Critical parts of the instance may be exposed to unauthorized access or manipulation.
Functional impact	None
Dependencies and prerequisites	None

Honor admin override ACLs

The *glide.security.admin.override.accessterm* property controls whether admins can control override access control list (ACL) evaluation.

The *glide.security.admin.override.accessterm* property controls how the platform decides whether an administrator can bypass an access rule when a resource (for example, a table, a field) has more than one access rule applied to it. Each individual access rule can be configured to grant or deny an admin override on its own.

When this property is set to its recommended value of **true**, the per-rule setting is honored individually. A rule explicitly configured to deny an admin override still blocks the administrator even if another rule on the same resource permits one. When set to **false**, the bypass decision is instead made at a broader, combined level. This can let an administrator through even though one of the applicable rules was specifically configured to block the override.

Ensure that the property *glide.security.admin.override.accessterm* system property is set to **true**.

More information

Attribute	Description
Configuration name	*glide.security.admin.override.accessterm*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Access control
Security risk	• Severity score: 3.8 • CVSS rating: Low • Security risk details: When access checks are evaluated coarsely, a privileged user can access a resource despite rules set to deny override. This allows the most restrictive protection to be ignored in favor of a more permissive rule on the same resource. Protected data can be set to readable or writable, risking unauthorized access to sensitive information.
Functional impact	Changing this property to **true** affects only elevated-admin access decisions on resources governed by more than one access rule; regular users and single-rule resources see no behavior change. After the change, test contextual security scenarios where an admin role is granted access to a field or record through multiple layered rules, confirming that a rule explicitly configured to deny override still blocks the admin as expected. No service availability impact is expected since the change only tightens an authorization decision path.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Prevent inactive users from logging in

Configure this property to control if inactive users can authenticate on your instance.

When the *glide.authenticate.only.allow.active.user.login* system property is not set to **true**, users in the User [sys_user] table marked inactive can still login to the instance. Users may be marked inactive if they no longer have permission to login (such as during termination from a company).

Set the *glide.authenticate.only.allow.active.user.login* property value to the recommended value of **true** (recommended), to ensures the users in the User [sys_user] table marked inactive can't log in to the instance and are locked out.

More information

Attribute	Description
Configuration name	*glide.authenticate.only.allow.active.user.login*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 7.5 • CVSS score: High • Security risk details: Inactive users may still access the instance and any data they could previously access.
Dependencies and prerequisites	None

Prevent unauthenticated roleless ACL in scripted ACLs

The *glide.security.allow_unauth_roleless_acl* property controls whether scripted Access Control Lists (ACLs) can grant access to unauthenticated users when the ACL is otherwise roleless.

When set to `true`, ACLs containing script may grant access to unauthenticated users. Setting this property to `false` prevents unauthenticated users from accessing resources protected by roleless scripted ACLs.

Confirm that the property *glide.security.allow_unauth_roleless_acl* is set to `false`.

More information

Attribute	Description
Configuration name	*glide.security.allow_unauth_roleless_acl*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	`false`
Default value	false
Fallback value	false
Category	Access control
Security risk	• Severity score: 7.5 • CVSS rating:High

Attribute	Description
	• Security risk details: When set to `true`, unauthenticated users unauthenticated users can view, create, or delete information that should be restricted to logged-in users.
Functional impact	When set to `true`, anonymous or guest visitors bypass login for pages, records, or actions. Setting it to `false` keeps the login requirement in place for roleless ACLs.
Dependencies and prerequisites	None

Prevent Unauthenticated Access to Virtual Agent Embedded Web Client

Learn how to configure the *sn_va_web_client_app_embed* table to block unauthenticated users from accessing embedded web clients.

The UI page *sn_va_web_client_app_embed*, which is an embedded web client for Virtual Agent, contains the ACL marked 'true' in the sys_public table Out of Box. It has been confirmed that there are use cases where public accessibility is needed however this is not a security best practice to set it to default publicly accessible.

Deactivate ui page *sn_va_web_client_app_embed* from the Public Pages [sys_public] table if embedded web client is not needed for unauthenticated users

More information

Attribute	Description
Configuration name	**sn_va_web_client_app_embed**
Configuration type	UI Page(sys_ui_page_list.do)
Data type	table
Recommended value	The Public Pages [sys_public] table record with sys_id of `04b190547322300e985658b4cf6a7ef` does exist or is not active.
Default value	Not available (this is a table value)
Category	Access control
Security risk	• Severity score: 7.5 • CVSS score: High • Security risk details: Sensitive information may be exposed to unauthenticated users.
Dependencies and prerequisites	None

Restrict JSONP requests to trusted URLs

Specify trusted URLs for the AngularJS $http service to allow or reject JSONP requests.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Increase security on your instance by ensuring that only trusted URLs for the AngularJS $http service can allow/reject JSONP requests. JSONP requests are allowed to any URL if these properties are not configured and enabled.

Use the value of the **angular.jsonp.inclusion_list.urls** system property to define a list of URLs that are trusted and allow for this purpose. Set the value of the **angular.jsonp.inclusion_list.enabled** system property to **true** to limit allowed JSONP to only the URLs listed in **angular.jsonp.inclusion_list.urls**.

More information

Attribute	Description
Configuration name	*angular.jsonp.inclusion_list.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: Medium • CVSS score: 5.4 • Security risk details: Setting this property to **false** enables JSONP requests to any URL.
Dependencies and prerequisites	None

Prevent users from accepting warning to bypass CSRF validation

Reduce the risk of Cross-Site Request Forgery (CSRF) by preventing users from accepting warning to bypass CSRF validation.

The *glide.security.csrf.strict.validation.mode* system property prevents users from being able to accept a warning, which allows a potentially malicious request to be sent to the instance. This warning appears when a POST request fails due to having a mismatched anti-CSRF token belonging to one of the victim's other active sessions. If *glide.security.csrf.strict.validation.mode* isn't set to the recommended value of **true**, then an attacker can formulate a CSRF attack utilizing a leaked anti-CSRF token from a different active session belonging to the victim.

A POST request to an instance contains an anti-CSRF token within "sysparm_ck" or "X-UserToken" which matches the user's current session. If the anti-CSRF token is instead tied to one of the user's other active sessions, the POST request will return a 302 redirection to security_interceptor.do with a **Continue** button available to the user when this property is set to **false**.

Clicking this button will re-submit the request to the instance, except it will now having a valid anti-CSRF token. When this property is set to **true**, the 302 redirection to the security_interceptor.do page will not display a **Continue** button and the user isn't allowed to resubmit the request.

Attribute	Description
Configuration name	*glide.security.csrf.strict.validation.mode*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	
Security risk	• Severity score: 3.7 • CVSS rating: Low • Security risk details: A successful CSRF attack will allow an attacker to effectively perform any operation that the victim is able to perform.
Functional impact	None
Dependencies and prerequisites	None

Disable raw database query execution [Updated in Security Center 1.3 and removed in 2.0]

Control whether a user can perform raw SQL queries on the database.

The *glide.db.allow_unsafe_dbi_execute_sql* property enables users to perform raw SQL queries on the database, which can give access to tables and data outside of GlideRecord restrictions. If this property is not set to the recommended value of *false*, this allows for the calling of *dbi.executeStatement()* from a Glide Scriptable which can lead to malicious SQL statements being executed.

⚠ **Warning:** This property is both safe and no db override.

More information

Attribute	Description
Configuration name	*glide.db.allow_unsafe_dbi_execute_sql*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Category	Access control

Attribute	Description
Security risk	• Severity score: 7.2 • CVSS score: High • Security risk details: Not setting this property to **false** enables calling of *dbi.executeStatement()* from a Glide Scriptable.
Dependencies and prerequisites	None
References	Access Control Lists (ACLs)

Require authentication by default for client-callable script includes

By default, client-callable script includes that do not explicitly set visibility, are public. If needed, add the *glide.script.ccsi.ispublic* property to enable privacy control over all client-callable script includes accessed by public pages.

The *glide.script.ccsi.ispublic* system property makes sure that client-callable script-includes, also known as Ajax script includes, are not automatically made available to non-authenticated users. If *glide.script.ccsi.ispublic* is not set to the recommended value of **false**, then it allows script includes to be run as public scripts and grant unauthenticated users access to instance data.

Ensure that the property *glide.script.ccsi.ispublic* is set to **false**.

⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.script.ccsi.ispublic*

Security risk	• Severity score: 6.3 • CVSS score: Medium • Security risk details: Allowing a production instance to be evaluated as non-production can lead to information disclosure or denial of service.
Functional impact	None
Dependencies and prerequisites	None

Restrict access to background script

Use a system property to set a role requirement for accessing the Script Background module.

Use the *glide.script_processor.admin* system property to set a required role to access the **Scripts - Background** module. If this property isn't set to the recommended value of `background_script_admin` or another high privileged role, users with lower privileged roles are able to run background scripts on your instance.

Ensure the property *glide.script_processor.admin* is set to `background_script_admin`. This is also the default value.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.script_processor.admin*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	background_script_admin
Default value	background_script_admin
Fallback value	background_script_admin
Category	Access control
Security risk	• Severity score: 8.8 • CVSS score: High • Security risk details: Background scripts allow a complete bypass of the ACL system allowing full access to tables.
Functional Impact	Users without the role specified in the property are unable to access the **Scripts - Background** module, as intended.
Dependencies and prerequisites	None

Restrict access to emails with empty target table

Activate the *glide.email.email_with_no_target_visible_to_all* property to restrict user access to emails, unless they were the one who sent the email or have an admin role.

If the *glide.email.email_with_no_target_visible_to_all* system property isn't set to the recommended value of **false**, then low level users will have access to emails which are not their own.

Ensure that the property *glide.email.email_with_no_target_visible_to_all* is set to **false**.

More information

Attribute	Description
Configuration name	*glide.email.email_with_no_target_visible_to_all*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	FALSE

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Fallback value	false
Category	Access control
Security risk	• Severity score: 6.5 • CVSS rating: Medium • Security risk details: Emails without a target record are visible to all users, allowing unauthorized access to sensitive communication and violating data confidentiality principles.
Functional impact	Users are no longer able to see emails where target table is empty unless they are an admin or were the sender of the email.
Dependencies and prerequisites	None

Restrict MID Server users from authenticating using UI

Reduce risk from a compromised MID Server account by disallowing UI authentication.

MID Server service accounts are automated system accounts that facilitate secure communication between the ServiceNow instance and resources behind your organization's firewall. These accounts should operate under the principle of least privilege, meaning they should only possess the minimum permissions necessary to perform their designated functions. Allowing UI authentication for MID Server accounts creates an unnecessary attack surface.

For each MID Server user record in the User [sys_user] table, confirm that the **web_service_access_only** field is set to "true".

More information

Attribute	Description
Configuration name	User [sys_user] table and mid_server_user.web_service_access_only
Configuration type	User [sys_user] table (/sys_user_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	N/A
Category	Access control
Security risk	• Severity score: 3.8 • CVSS rating: Low • Security risk details: If a MID Server account is compromised, an attacker with UI access could use the web interface to modify configurations or access sensitive data within the ServiceNow environment.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	By restricting these accounts to web service access only (setting **web_service_access_only** to true for MID Server users), organizations help ensure that MID Server credentials can only be used for their intended purpose of service to service communication.
Functional impact	None
Dependencies and prerequisites	None

Restrict access to specific IP ranges plugin

Use the *com.snc.ipauthenticator* plugin to restrict access to specific IP ranges. Unless public access is intended for the instance, administrators should limit access to their assigned IP net blocks.

The *com.snc.ipauthenticator* plugin, when set to **true**, restricts access to specific IP ranges. Unless public access is intended for the instance, administrators should limit access to their assigned IP net blocks.

Ensure that the *com.snc.ipauthenticator* plugin is activated and there is at least one active IP access policy in the IP Address Access Controls [ip_access] table.

More information

Attribute	Description
Configuration name	• *com.snc.ipauthenticator* • *IP Address Access Controls [ip_access]*
Configuration type	• Plugin (/v_plugin_list.do) • Table record (/ip_access_list.do)
Data type	N/A
Recommended value	• The *com.snc.ipauthenticator* plugin is active. • The IP Address Access Controls [ip_access] table contains at least one active record.
Default value	• The *com.snc.ipauthenticator* plugin is active by default. • The IP Address Access Controls [ip_access] table contains no records by default.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Fallback value	• The *com.snc.ipauthenticator* plugin is active by default. • The IP Address Access Controls [ip_access] table contains no records by default.
Category	Access control
Security risk	• Severity score: 5.3 • CVSS rating: Medium • Security risk details: Allowing unrestricted public access to a ServiceNow instance without properly configuring the IP Address Access Control plugin exposes the system to unauthorized access and potential exploitation from any IP address, undermining network-level security and increasing the attack surface.
Functional impact	None
Dependencies and prerequisites	This plugin when set to true restricts access to specific IP ranges. Unless public access is intended for the instance, administrators should limit access to their assigned IP net blocks. An exclusion list (Deny) or an inclusion list (Allow) of IP addresses can be created through IP Address Access Control (ip_access_list.do). Before setting this property, you must activate the IP Range Based Authentication (com.snc.ipauthenticator) *com.snc.ipauthenticator* plugin. To learn more, see IP range based authentication and in the Steps to configure section (below). Ensure the plugin *com.snc.ipauthenticator* is activated and there is at least one active IP access policy in the table ip_access.

Restrict knowledge bases access

The *glide.knowman.block_access_with_no_user_criteria* property is used to control the read/write access of users on knowledge based articles.

The *glide.knowman.block_access_with_no_user_criteria* system property is used in knowledge record user criteria security. If *glide.knowman.block_access_with_no_user_criteria* isn't set to the recommended value of **true**, then knowledge bases without `can read` or `can contribute` user criteria are readable and writable by all users.

Ensure the property *glide.knowman.block_access_with_no_user_criteria* is set to **true**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.knowman.block_access_with_no_user_criteria*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	True
Fallback value	false
Category	Access control
Security risk	• Severity score: 9.1 • CVSS score: Critical • Security risk details: Knowledge bases lacking explicit "can read" or "can contribute" user criteria are accessible and editable by all users, potentially leading to unauthorized access and modification of sensitive knowledge content.
Dependencies and prerequisites	None
Functional impact	Denies access to a knowledge base when either Can Read or Can Contribute isn't specified.

Restrict permissions for CMDB model

Use the *csm_cmdb_model.customer_visible_flag* system property to limit customer access to data in the Product Models table as an additional access control to the CMDB model.

The *csm_cmdb_model.customer_visible_flag* system property is an additional access control to the CMDB model. If *csm_cmdb_model.customer_visible_flag* is not set to the recommended value of **true**, then any user with the sn_esm_user role and out of the box ACLs will have permissions to the CMDB model. Note that this role tends to be granted to external users.

Ensure that the property *csm_cmdb_model.customer_visible_flag* is set to **true**.

More information

Attribute	Description
Configuration name	*csm_cmdb_model.customer_visible_flag*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	false

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Access control
Security risk	• Severity score: 6.5 • CVSS rating: Medium • Security risk details: External users could unwillingly be given permissions to the CMDB model.
Functional impact	None
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Restrict platform analytics export to authorized roles

The *glide.par.export.allowed_roles* property is a comma-separated list of role names permitted to export Platform Analytics dashboards and visualizations to PDF or PPT format.

This property determines which roles can export Platform Analytics dashboards and visualizations. When this property is not configured, any user who can reach the export action is allowed to export, with no additional role check. When populated, only users holding at least one of the listed roles may export; all others are denied and logged.

This property only takes effect when the *glide.par.export.enabled* property is also set to `true`.

To configure this property:

1. Navigate to `/sys_properties_list.do` on the instance.
2. Set the *glide.par.export.allowed_roles* property to a comma-separated list of role names that should be permitted to export Platform Analytics content.

More information

Attribute	Description
Configuration name	*glide.par.export.allowed_roles*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String, Comma-separated list of role names
Recommended value	Customer-specified roles authorized to export Platform Analytics dashboards and visualizations
Default value	Empty (no role restriction)
Fallback value	Empty (no role restriction)
Category	Access control
Security risk	• By default, the *glide.par.export.allowed_roles* property is empty, allowing any authenticated user who can view a dashboard or visualization and reach its export

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	action to generate an export. No role-based restriction beyond whatever access already let them view it on screen. • Converting on-screen, view-only access into a downloadable file materially changes the risk profile of that data. An export can be freely shared, stored outside the instance, or removed from the organization's control. Unlike an on-screen view, there is no way to revoke or audit it after the fact. This applies to every user who can reach the export feature, not a narrow population of privileged users.
Dependencies and prerequisites	This property has no effect unless the *glide.par.export.enabled* property is also set to `true`. If the *glide.par.export.enabled* property is set to `false`, export is already turned off entirely.
Functional impact	Populating this property restricts export to only the listed roles. Users without one of those roles will not be able to see or trigger export actions. This may be a visible change for existing users who previously exported without any role requirement. Instance owners should identify which roles genuinely need to distribute exported dashboard content and list only those roles. There is no single correct role list that applies to all instances, because this depends on each organization's own reporting and data-handling policies.

Restrict unauthenticated access to attachments

Restrict unauthenticated access to image attachments using a system property.

Use the *glide.image_provider.security_enabled* property restrict unauthenticated access to image attachments. If set to `true`, images are visible to any authenticated user but no unauthenticated user. If set to `false`, images are visible to anyone with a URL to the attachment. Thumbnails of an attached image maintain the same policy as the original attached image and are accessible to the same set of users as the original attached image. When this property is enabled, more fine grained access control for unauthenticated users is obtained through entries in the Security Allow/Deny List Entities [sys_security_restricted_list] table and through the declaration of public KB articles for those images attached to KB articles. These exceptions to the default policy for unauthenticated users when this property is `true` are applied in the following order.

Note: In these exceptions, "parent table" refers to the table of the original image attachment from which a thumbnail is generated.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

1. If the table of an attached image or parent table of a thumbnail image is deny-listed in the Security Allow/Deny List Entities [sys_security_restricted_list] table, access is denied to the image/thumbnail.
2. If the table of an attached image or parent table of a thumbnail image is allow-listed in the Security Allow/Deny List Entities [sys_security_restricted_list] table, access is granted to the image/thumbnail.
3. If the table of an attached image or parent table of a thumbnail image is included in a public KB article, access is granted to the image/thumbnail.

Ensure that the property *`glide.image_provider.security_enabled`* is set to `true`. If the property does not exist on the System Properties [sys_properties] table, the default value is `false`.

More information

Attribute	Description
Property name	*`glide.image_provider.security_enabled`*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Recommended value	true
Default value	true
Fallback value	false
Functional impact	If the property was previously `false` and then is set to `true`, unauthenticated users can no longer be able to access image attachments unless explicitly allowed using one of the exclusion procedures.
Security risk	• Severity Score: 6.5 • CVSS Rating: Medium • Security Risk Details: If the property is set to `false`, image attachments are visible to anyone authenticated or unauthenticated with a URL to the attachment. This may lead to sensitive information leaks. To avoid these, set the property to `true` and ensure any exceptions to the default policy when the property is `true` are properly configured.

Restrict access to custom journal entries [Updated in Security Center 1.3 and removed in 2.0]

Use the *glide.live_feed.custom_journal.acl_check_enabled* property to respect ACL's on custom journal fields.

If *glide.live_feed.custom_journal.acl_check_enabled* is not set to the recommended value of true, then all users to be able to see all journal entries within the life feed feature. Setting property to true will respect ACL's on custom journal fields which is a good to have feature.

More information

Attribute	Description
Property name	*glide.live_feed.custom_journal.acl_check_enabled*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	To control which users see which journal entries based on ACLs.
Recommended value	true
Default value	true
Configuration type	Boolean.
Security risk	(Moderate) When set to true, only the custom journal entries which pass ACL will be shown in Live Feed, otherwise, all users will be able to see all journal entries.

To learn more about adding or creating a system property, see Add a system property.

Restrict flow context read access

Use the *com.snc.process_flow.reporting.require_flow_access* property to enforce if an additional access check is required for a user to read a flow check.

When the *com.snc.process_flow.reporting.require_flow_access* system property is set to a value of **true**, there is an additional access check for a user trying to read a flow context. A user must have access to the parent flow to be able to read the flow context.

Ensure that the *com.snc.process_flow.reporting.require_flow_access* system property is set to **true**

More information

Attribute	Description
Configuration name	*com.snc.process_flow.reporting.require_flow_access*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Fallback value	true
Category	Access control
Security risk	• Severity score: 2.7 • CVSS score: Low • Security risk details: There may be minor information disclosure if this property is not set securely.
Dependencies and prerequisites	None
Functional impact	When this property is enabled, the security for reading flow context records are increased. The instance enforces that a user trying to read the flow context has read access to the parent flow as well.

Restrict Impersonation to Admin

The *glide.sys.permissive.impersonate* property can be used to prevent non-admin roles from impersonating other users.

When the *glide.sys.permissive.impersonate* system property is set to a value of **false**, only users with the *admin* role may impersonate. When this value is set to **true**, users may be able to make use of application components that expose impersonation APIs to impersonate a higher privileged user.

Ensure that the property *glide.sys.permissive.impersonate* is set to a value of **false**. If this property does not exist, the default value is **false**.

⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.sys.permissive.impersonate*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Access control

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 6.7 • CVSS score: Medium • Security risk details: May result in unauthorized resource access if these application components are misconfigured.
Dependencies and prerequisites	None
Functional impact	Non-admin users can access Impersonation features with some customizations to other scripts and UI pages. However, it is essential to ensure that only the correct users are granted access to these features. **Note:** When *glide.sys.permissive.impersonate* is set to true, Non-admin users with the *impersonate* role can still impersonate.

Restrict script authorship to authorized users only

The *glide.security.scripting_governance.enabled* property controls whether users must hold the script-writer role to create or modify executable script content across the platform.

When this property is enabled, users must hold the script-writer role to author or import records containing executable script content. Script content includes business rules, email templates, conditions, workflows, and HTML or XML code.

When this property is turned off, any user can create or modify code without authorization. Disabling this property removes a critical access boundary and allows any user, including low-privilege, guest, or malicious accounts, to inject arbitrary code into the system.

Important: This property is a foundational security control that prevents unauthorized code execution. Disabling it exposes the platform to significant security risks including privilege escalation, data exfiltration, and system compromise.

To configure this property:

- Navigate to /sys_properties_list.do on the instance.
- Ensure *glide.security.scripting_governance.enabled* doesn't exist in the sys_properties table or is set to `true`.

Attribute	Description
Configuration name	*glide.security.scripting_governance.enabled*
Configuration type	System Properties (`/sys_properties_list.do`)
Data type	Boolean
Recommended value	true

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Default value	true
Fallback value	true
Category	Access control
Security risk	• Severity score: 4.3 • CVSS rating: Low • Security risk details: Disabling script governance removes the authorization gate on code authorship platform-wide. Any user can create or modify executable scripts that run with system privileges. An attacker with low-privilege or guest access can inject malicious code into business rules, conditions, or workflows. The code executes automatically, enabling data theft, privilege escalation, and persistent backdoors. This completely undermines platform security and enables full system takeover.
Functional impact	None
Dependencies and prerequisites	None

Enable security jump start plugin (ACL Rules)

Activate the Security Jump Start (ACL Rules) (com.snc.system_security) plugin to create several important ACLs that validate the Access Controls on some of the key system tables within the ServiceNow AI Platform.

Security Jump Start (ACL Rules) (com.snc.system_security) plugin creates several important ACLs that validate the Access Controls on some of the key system tables within the Now Platform. These rules provide a jump-start on securing many system tables, making it easier for an organization to get an instance into production. The Security Jump Start (ACL Rules) plugin is installed automatically on all new instances.

Ensure that the Security Jump Start (ACL Rules) (com.snc.system_security) plugin is activated.

More information

Attribute	Description
Configuration name	*com.snc.system_security*
Configuration type	System Properties (/sys_properties_list.do)
Data type	N/A
Recommended value	N/A
Default value	N/A
Fallback value	N/A
Category	Access control

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 8.1 • CVSS rating: High • Security risk details: Gaps in access control can allow unauthorized users to view, modify, or delete sensitive data, undermining data integrity, confidentiality, and compliance with organizational security policies.
Functional impact	None
Dependencies and prerequisites	None

Use of secure insert multiple operation within import set API

Use the *com.glide.import_set_api.insert_multiple_optimize* property to control whether *GlideRecordSecure* or *GlideRecord* is used for the Insert Multiple operation within the Import Set API.

The *com.glide.import_set_api.insert_multiple_optimize* system property controls whether GlideRecordSecure or GlideRecord is used for the Insert Multiple operation within Import Set API.

If this property is set to **false**, then GlideRecordSecure will be used to insert records and Table level ACLs will be evaluated.

If this property is set to **true**, then GlideRecord will be used to insert records and Table level ACLs will not be evaluated.

Ensure that the property *com.glide.import_set_api.insert_multiple_optimize* is set to **false**.

Note: If this property must be set to **true**, then you must ensure that the *Import Set API Insert Multiple* REST Endpoint ACL (sys_id: 3101b770ff2211105cf343d0653bf182) is active and also audit user's who have the *import_transformer* role.

More information

Attribute	Description
Configuration name	*com.glide.import_set_api.insert_multiple_optimize*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Access control
Security risk	• Severity score: 6.5 • CVSS score: Medium

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Security risk details: If this property is not set to the recommended value of **false**, then a low privilege user may be able to insert data into tables outside the scope of their privileged roles.
Dependencies and prerequisites	None
Functional impact	This property optimizes the performance of Import Set API by using GlideRecord to save data. When the parameter is set, it requires an integration user to have the import_transformer role to access the API.
References	https://developer.servicenow.com/blog.do?p=/post/gliderecord-vs-gliderecordsecure

Enforce SOAP request strict security

Use the *glide.soap.strict_security* property to enforces web service security.

If the *glide.soap.strict_security* system property is not set to the recommended value of **true**, then users do not need a SOAP role to make requests of non-public pages when the high security or web service plugin is installed.

Ensure the property *glide.soap.strict_security* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.soap.strict_security*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Access control
Security risk	• Severity score: 6.8 • CVSS rating: Medium • Security risk details: An unauthorized user can get access to sensitive content/data on the target instance.
Functional impact	None
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Required JMS connection factories

The *mid.property.jms.command.allowed_factory_names* property controls the Java Messaging Service (JMS) connection factories that the MID Server can use.

This property controls the Java Messaging Service (JMS) connection factories that the MID Server can use. It is intended for a few select factories needed by plugins for JMS activity or action. Including additional factories could be a step in a chain of attack for vulnerabilities such as JNDI insertion that rely on capabilities an attacker can leverage in allowed factories. To prevent the possibility of any leveraged vulnerability, do not include factories beyond the necessary defaults.

Review the list of names provided to the mid property *mid.property.jms.command.allowed_factory_names*. Ensure any additional factory names beyond the default of `connectionFactory, queueConnectionFactory, topicConnectionFactory` are necessary.

See the following documentation for updating this and other mid server properties: MID Server properties

More information

Attribute	Description
Configuration name	*mid.property.jms.command.allowed_factory_names*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Default value	*connectionFactory, queueConnectionFactory, topicConnectionFactory*
Recommended value	*connectionFactory, queueConnectionFactory, topicConnectionFactory*
Category	Access control
Security risk	• Severity score: 4.1 • CVSS score: Medium • Security risk details: Expanding the set of Java Messaging Service (JMS) connection factories beyond the necessary defaults introduces a significant risk because it increases the attack surface for exploitation techniques such as JNDI injection. Allowing additional factories can enable attackers to leverage insecure configurations or vulnerabilities in messaging components as part of a broader attack chain, potentially leading to remote code execution or system compromise. Restricting factories to only those required by core functionality is essential to maintain a secure posture.
Dependencies and prerequisites	None

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Restrict Global App Development by Role

Use the *sn_g_app_creator.allow_global* property to control which users can create applications in the global scope using the Guided Application Creator.

The *sn_g_app_creator.allow_global* system property controls which users can create applications in the global scope using the Guided Application Creator. If *sn_g_app_creator.allow_global* is set to the recommended value of **false**, users need the sn_g_app_creator.global role to create an application in the global scope using Guided Application Creator. If *sn_g_app_creator.allow_global* is set to the insecure value of **true** then all users with only the base role "sn_g_app_creator.app_creator" can create an application in the global scope using Guided Application Creator. Applications in the global scope do not contain scope protections allowing a developer to access greater features and functions beyond a specific scope.

Ensure the property *sn_g_app_creator.allow_global* is set to **false** or does not appear in the System Properties [sys_properties] table. If the property is not present in the System Properties [sys_properties] table the secure default is used.

More information

Attribute	Description
Configuration name	*sn_g_app_creator.allow_global*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	Default value
Fallback value	false
Category	Access control
Security risk	• Severity score: 3.3 • CVSS score: Low • Security risk details: Limiting global application development to users with the additional role follows the principle of least privilege.
Dependencies and prerequisites	None
Functional impact	Enhanced the API (/api/now/templates) to validate the create global application ACL and property.

Review extraneous explicit role access control conditions [Removed in Security Center 1.5]

The Explicit Roles plugin is recommended to mandate that all users have either the snc_internal role to access internal resources, or the snc_external role to access external resources.

After the installation of this plugin, all existing users are assigned the snc_internal role, and existing access control lists (ACLs) are populated with the role conditions. Due to automation logic or intervention by an instance admin, the snc_internal or snc_external roles may be incorrectly added to an ACL that already contains a more strict role requirement. Since ACL

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

role evaluation will pass for any user containing any role mapped to an ACL, the addition of snc_internal or snc_external may be too broad for the intended purpose of an ACL. This could lead to data leakage if a low privileged user is granted access through the ACL.

For example, it would be unnecessary for both the snc_internal and the admin roles to be mapped to the same ACL within a table. The ACL is meant to grant access to admins, in which case the snc_internal role is a mistake. Or, the ACL is meant to grant access to all snc_internal users which makes the admin role unnecessary. When the Explicit Roles plugin is installed, review the ACLs which contain a role condition for snc_internal or snc_external while also containing a condition for another role. If the roles are able to function for a specific use case, then the finding should be periodically reviewed.

Important: This hardening setting will be removed in the next Security Center v1.5 store patch release and future versions. An Instance Scan suite called "Explicit Roles ACL Config Check Suite" is available in the Washington release. We recommend that you review the findings of this new Instance Scan.

Specify URL allow list for cross-origin iframe communication

Use a system property to specify which domains you trust for cross-origin communication.

Use the *glide.ui.concourse.onmessage_enforce_same_origin_whitelist* property to enable cross-origin communication between iframes from trusted domains you specify in an inclusion list. This property specifies list of trusted origins for message propagation (sent via window.postMessage) in the UI. If this property isn't set to a list of trusted/allowed origins for cross domain messaging, then cross origin messages can be allowed from domains which contain malicious scripts. The property values should contain a list of origins should be separated by a comma. If the property value is empty then all domains are blocked.

Ensure that the *glide.ui.concourse.onmessage_enforce_same_origin_whitelist* system property contains only a list of trusted domains to be used for cross origin messaging. If the list is empty no domains are allowed.

More information

Attribute	Description
Configuration name	*glide.ui.concourse.onmessage_enforce_same_origin_w*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	a comma separated list of trusted domains or empty
Default value	empty
Fallback value	empty
Category	Access control
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: Invalid trusted origins can allow untrusted domains to inject malicious payloads via window.postMessage, leading to cross-origin attacks such as data exfiltration, session hijacking, UI manipulation or DOM based XSS. If a web page

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	contains event handlers that do not perform proper origin validation, a web page, or script from any origin, can communicate with it. It can also initiate any functionality performed by the event handler. Communication with iframes from other domains is a security risk.
Functional impact	If you don't add intended domains to the inclusion list, cross-origin messages from that domain are not allowed.
Dependencies and prerequisites	None

Set guest user for soap requests

Configure this property to control the level of access of unauthenticated SOAP requests.

Use the *com.glide.soap.guest_user* system property to control the access level of unauthenticated SOAP requests. If this property isn't set to the recommended value of `soap.guest` or is set to a user with limited privileges, then SOAP requests execute on behalf of this user.

Ensure the property is set to `soap.guest` to ensure an appropriate level of access for unauthenticated SOAP requests.

More information

Attribute	Description
Configuration name	
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	soap.guest
Default value	soap.guest
Fallback value	soap.guest
Category	Access control
Security risk	• Severity score: 8.1 • CVSS score: High • Security risk details: Unauthenticated SOAP requests can allow unauthorized access if not properly restricted. Evaluating these requests against a minimally privileged user helps reduce the risk of exposing sensitive operations. Failure to enforce this control may result in elevated access and compromise system integrity.
Functional impact	SOAP requests are restricted to the permissions of the soap.guest user. If an integration relies on a resource that does not have the appropriate ACLs for soap.guest, those requests will result in permission denials.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Dependencies and prerequisites	None

Disable public access to favorites [Updated in Security Center 1.3 and 2.0]

Use the *glide.ui.magellan.favorites.allow_public* to specify whether unauthenticated users are allowed to see **Favorites** in the navigator.

Public Access to Favorites is compliant when *glide.ui.magellan.favorites.allow_public* is set to **false**.

More information

Attribute	Description
Property name	*glide.ui.magellan.favorites.allow_public*
Configuration type	System Properties (/sys_properties_list.do)
Configure in Instance Security Center	Yes
Purpose	Control if unauthenticated users are allowed to see **Favorites** in the navigator.
Type	true/false
Recommended value	*false*
Security Dependencies	Set *glide.ui.magellan.favorites.allow_public* to **false**.
Functional impact	(Medium) Enabling this property acts as a layer of protection from unauthorized users.
Security risk	(Medium) If this property isn't enabled, there's a risk of unauthorized access to sensitive data.
References	Configure favorites option

Enable SNC access control plugin

Activate the SNC Access Control (com.snc.snc_access_control) plugin to control access to your instances by Customer Service and Support personnel.

Prevent ServiceNow Customer Service and Support personnel from accessing the instances without your express permission by enabling the SNC Access Control (com.snc.snc_access_control) plugin. Although all access to your instance is audited, you may prefer to control this access. This access method is fully auditable and tracked.

Note: Other authorized ServiceNow Operations personnel, in their capacity to support and manage the product, are required to perform administrative actions on the underlying infrastructure. Enabling this plugin may affect support service levels and the Availability SLA. Availability SLA is then measured from the time that Support staff personnel are granted access to your instance.

Ensure that the SNC Access Control (com.snc.snc_access_control) plugin is activated.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Plugin Name	`com.snc.snc_access_control`
Configuration type	System Definition > Plugins
Category	Access control
Purpose	Prohibits Customer Service and Support employees from accessing the instance
Recommended value	Active
Default value	None. This is a plugin, not a Glide property, so there is no default value. The plugin is not installed by default.
Role required	The customer administrator can't activate this plugin. It must be explicitly requested because it requires elevated privileges to activate the plugin.
Security risk rating	3.3
Functional impact	If this plugin is inactive, all Customer Service and Support employees can access the customer's instance. Enabling the plugin enables the customer to restrict access to authorized Customer Service and Support employees only.
Security risk	(High) Unnecessary exposure of instance access to wider group of people.
References	ServiceNow access control

Steps to configure

1. To request the plugin, follow the steps in Activate ServiceNow access control. Customers must request the SNC Access Control plugin (com.snc.snc_access_control) from HI.
2. To enable SNC access control, follow the steps in Configure ServiceNow access control. Configure an access control record to specify one or more Customer Service and Support employees that have permission to log in your instance.

Use Document Classification to limit publicly accessible documents [New in Security Center 7.0]

Control public access to permalinked documents using system properties.

Note: This hardening setting is not a part of the hardening baseline. It does not appear in Security Center hardening pages and affect your hardening score.

By default, the Document Management plugin includes these classifications:

- **public**
- **restricted**
- **confidential**
- **none** (no classification provided)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Use the *com.snc.documents.permalink.allowed_classifications* to create a list of document classifications. Documents under these classifications (and documents without classification) are publicly accessible to any unauthenticated users with an appropriate link.

Use this property to control public access to document permalinks. Previously, these links were publicly accessible to anyone with the link. The value of this property depends on your specific needs. You may have additional custom document categories that may need to be added to this property to enable public access.

Set the *com.snc.documents.permalink.allowed_classifications* property value to a comma-separated list of document classifications. Documents with these classifications are publicly accessible by unauthenticated users.

If this property isn't present in the System Properties [sys_properties] table, it defaults to an empty list. In this case, only documents with no classification are publicly accessible by unauthenticated users. The default value of this property is **public**, meaning that only documents classified as **public** or documents with no classification are accessible to unauthenticated users.

More information

Attribute	Description
Configuration name	*com.snc.documents.permalink.allowed_classificatio*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String list
Recommended value	public
Default value	public
Fallback value	<empty>
Category	Access control
Security risk	• Severity score: 5.3 • CVSS score: Medium • If a document category containing documents which shouldn't be publicly accessible is added to this property, it may expose sensitive information to unauthenticated users.
Functional impact	If a document category containing documents which should be publicly accessible isn't added to this property, it prevents those documents from being accessed.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Validate query ACLs on Glide DB functions [New in Security Center 7.0]

Control whether query ACLs are applied to Glide DB functions using system properties.

When the *glide.db.encoded_query.check_function_field_query_acls* system property is set to **true**, query ACLs (query_range and query_match) are validated by default on these Glide DB functions:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- glidefunction:position
- glidefunction:substring
- glidefunction:concat
- glidefunction:coalesce
- glidefunction:length

To validate these query ACLS on additional functions, add those functions to the *glide.db.encoded_query.force_query_range_on_functions* system property.

Set the *glide.db.encoded_query.check_function_field_query_acls* system property to **true**, or confirm that the property isn't on the System Properties [sys_properties] list.

More information

Attribute	Description
Configuration name	• *glide.db.encoded_query.check_function_field_quer* • *glide.db.encoded_query.force_query_range_on_func*
Configuration type	System Properties (/sys_properties_list.do)
Data type	• Boolean • String list
Recommended value	• true • glidefunction:position, glidefunction:substring, glidefunction:concat, glidefunction:coalesce, glidefunction:length
Default value	• true • glidefunction:position, glidefunction:substring, glidefunction:concat, glidefunction:coalesce, glidefunction:length
Fallback value	• true • glidefunction:position, glidefunction:substring, glidefunction:concat, glidefunction:coalesce, glidefunction:length
Category	Access control
Security risk	• Severity score:5.3 • CVSS score: Medium • If the *glide.db.encoded_query.check_function_field_quer*

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	system property exists and isn't set to a value of **true**, a logged-in user may be able to infer data blindly, leading to sensitive information disclosure.
Functional impact	Users may expect to see values from function fields but get blocked due to ACLs enforced on the function fields.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

API and web service

The API and Web Service category ensures that applications have appropriate authentication, authorization and session management, validate all input that traverses a trust boundary and include security controls for all API types.

Specific controls in this category address input validation by service type such as XDS schema validation for SOAP web services or Denial of Service protection for graphQL APIs.

Normalise REST API access policy key generation

The *glide.rest.policy.normalize_apply_all_fields* property controls how the platform builds lookup keys for REST API access policies when wildcard flags are set.

REST API endpoints on the platform can be protected by access policies. Each policy defines a scope by specifying which API path, HTTP method, and API version it covers. For each dimension, you can select either an exact value or an apply to all wildcard flag. When a request arrives, the platform builds a lookup key from the request attributes and searches a cache of active policies for a match.

This property controls a normalization step in the key-building process. A policy record can be in an inconsistent state where the **apply to all flag** for a dimension is set to `true`, but a specific value is also stored in the same record. This is a legacy data condition.

Without normalization enabled, the platform builds the lookup key using the specific value, even though the flag indicates all values should match. This causes the policy to only match requests with that exact value. With normalization enabled, when the **apply to all flag** is set, the specific value is discarded before the lookup key is built. This verifies the policy matches the full scope it declares.

Attribute	Description
Configuration name	*glide.rest.policy.normalize_apply_all_fields*
Configuration type	System Properties (`/sys_properties_list.do`)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	API and web service
Security risk	• Severity score: 6.5 • CVSS rating: Medium • Security risk details: Access policies on this platform are authorization controls. They determine which authentication requirements apply to which API endpoints. A policy misconfiguration caused by the inconsistent data results in a policy that is registered as active but silently never matches incoming requests outside its stale specific value. An administrator may believe a policy is enforcing an authentication requirement across all HTTP methods, all API versions, or all resources. But requests outside the stale specific value bypass the policy entirely. The attack surface is any API call that should have been governed by such a policy.
Functional impact	Setting this property to `true` changes how the policy lookup cache is populated at startup and after policy record change. Policies with the inconsistent data condition will have their effective scope corrected: they match all requests within the "apply to all" dimension. They no longer match only the stale specific value. Policies without the inconsistent data condition are unaffected. The cache is automatically invalidated when the property is toggled. The change takes effect without a restart. Enabling this property widens the enforcement scope of affected policies. This is the intended behavior. Before production rollout, verify that existing policy configurations see no unintended authentication requirements changes.
Dependencies and prerequisites	None

Validate SOAP content type

Use the *glide.soap.require_content_type_xml* property to enable validation of a content type as text/xml and protect against invalid SOAP requests.

If the *glide.soap.require_content_type_xml* system property is not set to the recommended value of **true**, then there is no validation for the SOAP request.

Ensure that the property *glide.soap.require_content_type_xml* is set to **true**.

⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.soap.require_content_type_xml*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	API and web service
Security risk	• Severity score: 8.8 • CVSS rating: High • Security risk details: This lack of validation can enable Cross-Site Request Forgery (CSRF) attacks, allowing malicious actors to trick authenticated users into sending unauthorized SOAP requests.
Functional impact	This remediation enables validation of SOAP content type for all the inbound SOAP requests. • If you are using a content type other than text/xml for inbound requests, it may cause potential failure of SOAP transactions. • If you are not using the correct MIME type, it could disrupt third-party integrations.
Dependencies and prerequisites	None

Prevent OAuth Clients from Using Implicit Grant

Use a system property to avoid the use of the implicit grant type.

The OAuth implicit grant was created to overcome a limitation between browsers and client-side applications (for example, single page applications) prior to the widespread adoption of Cross Origin Resource Sharing (CORS). Specifically, browsers' same-origin policy blocked the request that exchanged the OAuth authorization code with the OAuth access token. Since CORS support is universal, OAuth clients don't need to use the implicit grant, and implicit grant type requests fail by default.

Client IDs listed in the *glide.oauth.clients.allowed.for.implicit.grant* property can continue using the implicit grant type. Ensure that the property doesn't exist in the System Properties [sys_properties] table, or exists but doesn't contain a value.

Important: Changing an OAuth client to a different grant type may require code or configuration changes in the client application (outside of the ServiceNow platform).

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.oauth.clients.allowed.for.implicit.grant*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	<blank>
Default value	<blank>
Fallback value	<blank>
Category	API and web service
Security risk	• Severity score: 3.9 • CVSS score: low • Security risk details: The OAuth implicit grant type causes the authorization server to issue access tokens within the authorization response, making it vulnerable to access token leakage and access token replay. This means that an attacker can use the leaked or stolen access token at a resource endpoint. In the implicit grant, the authorization server returns an access token directly in the URL fragment, potentially causing problems: 1. This URL fragment may be stored in the browser history. 2. If the page subsequently loads images, or follows links to other domains, parts of the URL may leak via the referrer header. 3. Web servers, load balancers, and proxies may log full URLs. 4. Any JavaScript running on the page (including malicious, injected JS) can read the `window.location.hash` and extract the token. To avoid these issues, use the authorization code grant type rather than the implicit grant type when a human/interactive user is delegating authorization to the client. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	The implicit grant type request fails out of the box. Any OAuth clients with the implicit grant type that aren't added to the property fail by default. If you haven't defined any OAuth clients that use the implicit grant type, there is no impact. **Note:** Changing an OAuth client to a different grant type may require code or configuration changes in the client application (outside of the ServiceNow platform).
Dependencies and prerequisites	None

Require authorization for PDF requests

Use the *glide.basicauth.required.pdf* property to designate if incoming PDF requests should require basic authentication.

If *glide.basicauth.required.pdf* is not set to the recommended value of **true**, the Basic Authentication for PDF format export processor is disabled. This also happens when combined with a wrong role within the guest_user related property (For example a high privileged user such as Admin). This leads to unauthenticated access to instance data.

Ensure the property *glide.basicauth.required.pdf* exists in the System Properties [sys_properties] table and is set to **true**.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	API and web service
Security risk	• Severity score: 7.5 • CVSS rating: High • Security risk details: Unauthenticated access to PDF export data, when combined with misconfigured guest user role, poses a significant risk of unauthorized data exposure.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while retrieving data from tables/pages in the form of PDF data on the instance. • It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions. To learn more, see Web service import sets.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Require Authentication on Event Management HTTP Processor [New in Security Center 1.3, Updated in 1.5, and removed in 2.0]

Learn how to establish secure basic authentication for inbound Amazon Simple Notification Service (SNS) requests when the Event Management plugin (*com.glideapp.itom.snac*) is enabled.

If the *glide.basicauth.required.evtmgmthttpprocessor* property isn't set to the recommended value of **true**, and the Event Management plugin (*com.glideapp.itom.snac*) is active, then basic authentication is not required for all inbound Amazon Simple Notification Service (SNS) requests. This can lead to unauthenticated access to instance data.

To remediate this security risk, ensure that *glide.basicauth.required.evtmgmthttpprocessor* is set to**true** and that *com.glideapp.itom.snac* is active.

More information

Attribute	Description
Configuration name	*glide.basicauth.required.evtmgmthttpprocessor*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	API and web service
Security risk	• Severity score: 7 • CVSS score: High • Security risk details: Not setting*glide.basicauth.required.evtmgmthttpprocesso*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	to the recommended value of true, and not activating the *com.glideapp.itom.snac* plugin causes basic authentication not to be enabled for inbound SNS requests. This could lead to unauthenticated access to instance data.
Dependencies and prerequisites	None
References	• https://docs.aws.amazon.com/sns/latest/dg/welcome.html • Access control
Functional impact	If *glide.basicauth.required.evtmgmthttpprocessor* is not set to the recommended value of True, and if the Event Management plugin (com.glideapp.itom.snac) is active, then basic authentication is not required for all Inbound Amazon Web Services SNS requests. This can lead to unauthenticated access to instance data.

Require authorization for SOAP requests

Use the *glide.basicauth.required.soap* property to designate if incoming SOAP requests should require basic authorization.

The *glide.basicauth.required.soap* property controls whether basic authentication is required to make a Simple Object Access Protocol (SOAP) request to an instance. If the *glide.basicauth.required.soap* property is not set to **true**, unauthenticated users performing SOAP operations are mapped to the soap.guest user.

This may enable an unauthenticated user to perform operations on the instance as if a logged in user to the instance. There may be additional impact if the user define within *com.glide.soap.guest_user* is assigned additional roles. The property *glide.soap.require_ws_security* (default false) controls whether WS-Security header validation is mandatory. When set to **false**, requests without WS-Security are allowed if other auth mechanisms (basic auth, session) are present.

When set to **false**, both properties allow unauthenticated SOAP requests to map to the guest user and execute without credential validation, enabling unauthorized data export and system operations.

Ensure the *glide.basicauth.required.soap* property exists and is set to **true**. Alternatively, configure the instance for Web Services (WS) Security by setting the *glide.soap.require_ws_security* property to **true** and following the product documentation to configure WS security profiles. If the property doesn't exist in the sys_properties table, add it to the table.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	• *glide.basicauth.required.soap* • *glide.soap.require_ws_security*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	• false • false
Default value	• true • false
Fallback value	• true • false
Category	API and web service
Security risk	• Severity score: 8.1 • CVSS rating: High • Security risk details: When set to **false**, both properties allow unauthenticated SOAP requests to map to the guest user and execute without credential validation, enabling unauthorized data export and system operations.
Functional impact	Disabling either property relaxes SOAP request authentication requirements. Basic authentication is optional or WS-Security validation is optional, allowing unauthenticated or weakly-authenticated requests to proceed.
Dependencies and prerequisites	None

Require authorization for unload requests

Use the *glide.basicauth.required.unl* (useUnloadFormat) property to designate if incoming unload requests should require basic authentication.

The *glide.basicauth.required.unl* system property performs authentication while retrieving data from tables/pages in the form of unload data on the instance. If *glide.basicauth.required.unl* isn't set to the recommended value of **true**, then the Basic Authentication for the UNL format export processor is disabled. This also could be combined with a wrong role within the guest_user related property, this will lead to unauthenticated access to instance data.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Ensure the property *glide.basicauth.required.unl* exists in the System Properties [sys_properties] table and is set to **true**.

More information

Attribute	Description
Configuration name	*glide.basicauth.required.unl*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	API and web service
Security risk	• Severity score: 7.5 • CVSS rating: High • Security risk details: This property may allow unauthenticated access to unload data exports, especially when combined with misconfigured guest user roles, creating a serious risk of unauthorized exposure of instance configuration and data.
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. It performs this authentication while retrieving data from tables/pages in the form of unload data on the instance.
Dependencies and prerequisites	None

Require authorization for csv requests

Use the *glide.basicauth.required.csv* property to designate if incoming CSV (Comma-Separated Values) requests should require basic authentication.

More information

If the *glide.basicauth.required.csv* system property isn't set to the recommended value of **true**, then Basic Authentication for CSV format export processor is disabled. This also happens when combined with a wrong role within the guest_user related property (Ex: high privileged role). This will lead to unauthenticated access to instance data.

Ensure the property *glide.basicauth.required.csv* exists in the System Properties [sys_properties] table and is set to **true**.

⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.basicauth.required.csv*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	API and web service
Security risk	• Severity score: 7.5 • CVSS rating: High • Security risk details: Unauthenticated access to CSV export data, when combined with misconfigured guest user role, poses a significant risk of unauthorized data exposure.
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while retrieving data from tables/pages in the form of CSV data on the instance. • It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions. To learn more, see Retrieving data from a CSV formatted file.
Dependencies and prerequisites	None

Require authorization for excel requests

Use the *glide.basicauth.required.excel* property to designate if incoming Excel requests should require basic authentication.

If the *glide.basicauth.required.excel* system property is not set to the recommended value of **true**, then this will disable Basic Authentication for Excel format export processor. This also happens when combined with a wrong role within the guest_user related property (For example a high privileged user such as Admin).

Ensure that the property *glide.basicauth.required.excel* exists in the System Properties [sys_properties] table and is set to **true**.

⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	API and web service
Security risk	• Severity score: 7.5 • CVSS rating: High • Security risk details: Unauthenticated access to Excel export data, when combined with misconfigured guest user role, poses a significant risk of unauthorized data exposure.
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while retrieving data from tables/pages in the form of Excel data on the instance. • It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Require authorization for import requests

Use the *glide.basicauth.required.importprocessor* property to designate if incoming import requests should require basic authentication.

The *glide.basicauth.required.importprocessor* system property performs this authentication while importing data sources into the instance tables/pages.

It restricts any guest users who are currently accessing this data. If *glide.basicauth.required.importprocessor* isn't set to the recommended value of **true**, then unauthenticated users could access import processor. Additional access controls, such as ACLs, are still enforced, but this value allows a guest user import request to be processed and not summarily denied.

Fallback value	false
Category	API and web service
Security risk	• Severity score: 7.5 • CVSS rating: High • Security risk details: Unauthenticated access to JSON export data, when combined with misconfigured guest user role, poses a significant risk of unauthorized data exposure.
Functional impact	None
Dependencies and prerequisites	None

Require authorization for WSDL request

Use the *glide.basicauth.required.wsdl* property to designate if incoming WSDL (Web Services Description Language) requests should require basic authentication.

If *glide.basicauth.required.wsdl* system property is not set to the recommended value of **true**, then Basic Authentication for WSDL requests are turned off. WSDL is a protocol that is used to describe web services such as instance table schemas, and is not a mechanism for sharing the data within tables. Setting this property to **true** allows for disclosure of table schemas to unauthenticated users.

Ensure the property *glide.basicauth.required.wsdl* exists in the System Properties [sys_properties] table and is set to **true**.

Note: If you choose not to require basic authentication for incoming WSDL requests, you must modify Access Control (ACL) rules to enable guest users to access the WSDL content.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while retrieving data from tables/pages in the form of XSD data on the instance. • It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions. To learn more, see Non-interactive sessions.
Dependencies and prerequisites	None

Require authorization for script requests

Use the *glide.basicauth.required.scriptedprocessor* property to designate if incoming script requests should require basic authentication.

The *glide.basicauth.required.scriptedprocessor* system property determines whether basic auth is required to invoke a scripted processor. Any records accessed by the scripted processor still use other access controls, such as ACLs, before returning any data. If *glide.basicauth.required.scriptedprocessor* isn't set to the recommended value of **true**, then an attacker could access sensitive information such as an unauthenticated (guest) user attempting to access an email through the EmailDisplay sys_processor.

Ensure the property *glide.basicauth.required.scriptedprocessor* exists in the System Properties [sys_properties] table and is set to **true**.

⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.basicauth.required.scriptedprocessor*
Configuration type	System Properties (/sys_properties_list.do)

Attribute	Description
Security risk	• Severity score: 5.3 • CVSS rating: Medium • Security risk details: Omitting authentication from this processor will lead to unauthenticated access to instance schema data.
Functional impact	None
Dependencies and prerequisites	None

Require authorization for RSS requests

Use the *glide.basicauth.required.rss* property to designate if incoming RSS requests should require basic authentication.

The *glide.basicauth.required.rss* system property controls basic authorization for inbound RSS requests. If *glide.basicauth.required.rss* isn't set to the recommended value of **true**, then Basic Authentication for RSS format export processor is disabled. This also could be combined with a wrong role within the guest_user related property, this will lead to unauthenticated access to instance data.

Ensure the property *glide.basicauth.required.rss*exists in the System Properties [sys_properties] table and is set to **true**.

⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.basicauth.required.rss*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	API and web service
Security risk	• Severity score: 7.5 • CVSS rating: High • Security risk details: Unauthenticated access to RSS export data, when combined with misconfigured guest user role, poses a significant risk of unauthorized data exposure.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while processing RSS requests on the instance. • It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions. To learn more, see RSS feed generator.
Dependencies and prerequisites	None

Require authorization for API requests

Use the *glide.basicauth.required.api* property to enhance security for basic authorization for incoming REST requests.

If *glide.basicauth.required.api* isn't set to the recommended value of **true**, then Basic Authentication on API requests are disabled which leads to unauthenticated access to instance data.

Ensure the property *glide.basicauth.required.api* exists in the System Properties [sys_properties] table and is set to **true**.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.basicauth.required.api*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	API and web service
Security risk	• Severity score: 8.6 • CVSS rating: High • Security risk details: Unauthenticated access to API data, when combined with misconfigured guest user role, poses a significant risk of unauthorized data exposure.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	None
Dependencies and prerequisites	None

Architecture, design, and threat modeling

This broad control addresses high level design considerations and key elements to implement a secure application. This covers the tenants of availability, confidentiality processing integrity, non-repudiation and privacy. Additionally, elements of a secure software development lifecycle are included.

Capture audit records for Code Signing-protected records

Use the *sn_cse.com.snc.csf.vault_audit_enabled* property to control whether the system logs changes to Code Signing-protected code.

When this property is set to `true`, every creation, modification, or deletion of protected code is logged, allowing administrators to review who changed what and when. When inactive, no audit trail is created for protected code changes.

Note: This property only applies when Code Signing is activated on your instance. It has no effect on unprotected code or test and development environments.

More information

Attribute	Description
Configuration name	*sn_cse.com.snc.csf.vault_audit_enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Architecture, design, and threat modeling
Security risk	• Severity score:5.1 • CVSS rating:Medium • Security risk details: Disabling this property stops audit logging for protected records. Attackers or insiders with write access can modify or delete scripts, business rules, and configurations without leaving any trace, hiding their activity from audits and conformance reports. While this doesn't bypass access controls, it delays incident response and tampers detection—a critical concern for regulatory conformance.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	When enabled (the default), the system automatically records every change made to protected records in an audit log: who changed it, what changed, and when. Administrators can review this log for conformance and troubleshooting without any extra setup. This requires the Code Signing feature to be active and works automatically on production systems while skipping test and development environments to reduce log noise. Disabling the property stops these audit records from being created. It reduces database activity but removes the visibility teams require to track changes and verify conformance. The setting takes effect immediately without requiring a restart.
Dependencies and prerequisites	This property requires the Code Signing feature to be activated on your instance. It has no effect if Code Signing is not enabled.

Check impersonation on ACL evaluation in HR App [New in Security Center 1.3 and updated in 1.5]

Use the *sn_hr_core.impersonateCheck* property to prevent a user from impersonating another user and accessing their HR information.

A secure setting prevents an admin from seeing another user's HR information while using impersonation. An insecure setting for this property allows an admin to impersonate a user and access HR data such as survey results or audit records with the impersonated user's access. Due to the nature of this type of data, such as information which should be available only to the user themselves like email, this is not recommended. Setting *sn_hr_core.impersonateCheck* to true only allows access to HR information when the user is not impersonating any others.

More information

Attribute	Description
Configuration name	*sn_hr_core.impersonateCheck*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 2.7 • CVSS score: Low • Security risk details: An insecure setting for this property allows an admin to impersonate a user and access HR data such as survey results or audit records with the impersonated user's access.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Dependencies and prerequisites	None
Functional impact	When this property set to true, it prevents an admin from seeing another user's HR information while using impersonation. When set to false, it allows an admin to impersonate a user and access HR data such as survey results or audit records with the impersonated user's access. Due to the nature of this type of data, such as information which should available only to the user themselves like an email, this is not recommended. Setting sn_hr_core.impersonateCheck to true only allows access to HR information when the user is not impersonating any others.

Reduce the scope of the IP allow List for an instance

Use the *glide.ip.authenticate.strict* property to specify IP ranges that can make inbound connections on an instance.

Use the *glide.ip.authenticate.strict* property to reduce the scope of the IP allow list of an instance and restrict the IP addresses that ServiceNow personnel can use to make inbound/outbound connections to an instance. The exact IP ranges removed from the IP allow list by this property may be adjusted over time as the ServiceNow internal network changes. When set to true, *glide.ip.authenticate.strict* always guarantees an IP allow list that is equal to or more restrictive than the default.

When glide.ip.authenticate.strict is set to true:

A strict list of ServiceNow IP ranges replaces the default IP allow lists for inbound and outbound requests. This IP allow list, which starts with a more restrictive predefined set of allowed IP ranges, is replaced by the property glide.ip.authenticate.allow.secured.self_hosted_list if the instance is self-hosted.

When glide.ip.authenticate.strict is set to false:

The default IP allow list is used which contains a wider set of ServiceNow IP ranges. The default IP allow list is replaced by the contents of glide.ip.authenticate.allow.self_hosted_list if the instance is self-hosted.

Regardless of the value of *glide.ip.authenticate.strict* or if the instance is self-hosted, the allow list includes IP addresses in the *glide.custom.ip.authenticate.allow* and *glide.custom.ip.outbound.authenticate.allow* system properties, if defined.

All IP list properties share the same format, which is a comma separated range of IP addresses in IPv4 or IPv6 format. IP ranges are specified using a hyphen (10.0.10.14-10.0.10.19), using CIDR notation (10.0.10.0/24), or consist of a single IP address (10.0.10.5). At runtime, you can make additions to the IP allow list by adding entries to the IP Address Access Controls [ip_access] table. This table can also be used to explicitly deny IP ranges access to an instance.

The IP allowlist associated with this configuration is managed by ServiceNow and is not configurable by the customer.

Warning: The value for this property is a no DB override. It can't be altered or overridden.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	• *glide.ip.authenticate.strict* • *glide.ip.authenticate.allow.secured*
Configuration type	System Properties (/sys_properties_list.do)
Data type	• Boolean • String
Recommended value	• true • Managed by ServiceNow. Contains ServiceNow data center and secure VPN IP ranges. This value is deployed automatically and cannot be modified by customers.
Default value	• false • <empty>
Fallback value	• false • <empty>
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security Risk Details: Broader access increases the risk of unauthorized or unnecessary access to the instance by non-essential internal users, such as support or sales staff. It also reduces control over privileged access. Enforcing strict IP authentication limits connectivity to essential infrastructure, strengthening security and reducing exposure to insider threats or misconfiguration.
Functional impact	This should have no functional impact. It may restrict non-essential ServiceNow personal from accessing an instance. However, these are individuals that don't generally require access to such instances. If access is required, you can grant it on a case by case basis using the IP Address Access Controls [ip_access] table.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Disable legacy JQuery behavior

The *glide.jquery.legacy* is used to prevent older prepatched JQuery versions from being used which will introduce unpatched vulnerabilities in the library.

If *glide.jquery.legacy* is not set to the recommended value of **false**, then older prepatched JQuery versions are used which introduce unpatched vulnerabilities in the library. When **false**, integrates the JQuery 1.12.3 and 2.2.3 security patches. The system property is a fail-safe in case any organizations depend on the non-patched versions of angularJS to run their custom implementations.

Ensure the property *glide.jquery.legacy* is set to **false**.

More information

Attribute	Description
Configuration name	*glide.jquery.legacy*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	true
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 7.1 • CVSS rating: High • Security risk details: This update could potentially lead to security risks arising from attacks on vulnerabilities discovered in outdated JQuery library versions.
Functional impact	None
Dependencies and prerequisites	None

Disable GlideRecord scope fencing legacy behavior

The *glide.record.legacy_cross_scope_access_policy_in_script* property disables scope fencing allowing scoped apps to access global script interfaces. It was created as a patch to GlideRecord's cross scope access.

GlideRecord provided cross scope create and update access to tables that were not configured with that level of access. To prevent customers from having applications broken when this scoped access behavior was patched, the property *glide.record.legacy_cross_scope_access_policy_in_script* was created. When set to **true**, cross scope access falls back onto legacy behavior (insecure). This property disables scope fencing, allowing scoped apps to access global script interfaces.

Set the *glide.record.legacy_cross_scope_access_policy_in_script* system property to **false**. When not present in the System Properties [sys_properties] table, the default value is **true**.

More information

Attribute	Description
Configuration name	*glide.record.legacy_cross_scope_access_policy_in_s*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	true
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 5.0 • CVSS rating: Medium • Security risk details: It is best security practice to have scope fencing restrictions in place. Scoping ensures applications can only access resources with explicit access or within their scope, following the principle of least privilege. Disabling this feature could lead to confidentiality, availability, and integrity impacts.
Functional impact	None
Dependencies and prerequisites	None

Disable legacy AngularJS behavior [Removed in Security Center 2.2]

Use the *glide.angular.legacy* property to protect from potential security risks arising from attacks on vulnerabilities discovered in outdated AngularJS library versions.

Set *glide.angular.legacy* to the recommended value of **false** to prevent older prepatched angularJS versions from being used. Set the property to **true** to use older prepatched angularJS versions.

More information

Attribute	Description
Property name	*glide.angular.legacy*
Configuration type	System Properties (/sys_properties_list.do)
Category	Architecture, design, and threat modeling
Purpose	The system property is a failsafe in case any organizations depend on the non-patched versions of angularJS to run their custom implementations.
Recommended value	False
Configuration type	Boolean
Security risk	(High) Using older versions of angularJS could potentially lead to security risks arising from attacks on

Attribute	Description
	vulnerabilities discovered in outdated AngularJS library versions.
Security risk rating	7.1

Disable local login for users with Single Sign-On (SSO) enabled

Update user records to disable local login for users with Single Sign-On (SSO) enabled.

Users configured to use SSO authentication may be able to access the instance, or parts of the instance, with local credentials stored in the user_password field of their User [sys_user] record. This access applies to both interactive and non-interactive access for users who aren't locked out. Help prevent SSO-configured users from using local credentials to reduce the chance that valid local login credentials are stolen and used by malicious users.

Review Now Support Knowledge Base article KB1649420 for instructions on identifying and addressing accounts with local login still enabled on an instance with SSO enabled.

More information

Attribute	Description
Security risk	When SSO authentication is enabled for a user, it's best practice to prevent that user from logging in locally. This reduces the chance that the valid local login credentials are stolen and used to login by a malicious user.
Common Vulnerability Scoring System (CVSS) score	4.2
Common Vulnerability Scoring System (CVSS) rating	Medium
Functional impact	SSO configured users are able to log in with local credentials.
Dependencies and prerequisites	Single Sign-On must be enabled (the **glide.authenticate.multisso.enabled** system property set to **true**.)
Data type	N/A
Base system value	N/A
Fallback value	N/A
Recommended value	N/A

Disable unauthenticated published reports

Deactivate this property to prevent the user from publishing or accessing reports. This property disables the published reports feature in reporting.

If the *glide.report.published_reports.enabled* system property is not set to the recommended value of **false**, then reports stored on the instance can be made visible without authentication.

Ensure that the *glide.report.published_reports.enabled* system property exists in the System Properties [sys_properties] table and is set to the value **false**. If the property does not appear in the sys_properties table, add a new record.

More information

Attribute	Description
Configuration name	*glide.report.published_reports.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	true
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 6.5 • CVSS rating: Medium • Security risk details: Allowing unauthenticated access to sensitive data can cause inadvertent information disclosure to a malicious actor.
Functional impact	The user cannot publish reports.
Dependencies and prerequisites	None

Disable public access to favorites

Use the *glide.ui.magellan.favorites.allow_public* to specify whether unauthenticated users are allowed to see **Favorites** in the navigator.

If the *glide.ui.magellan.favorites.allow_public* system property is not set to the recommended value of **false**, then all unauthenticated users can access favorites of the same "Guest" user in the navigator.

Ensure the property *glide.ui.magellan.favorites.allow_public* is set to "**false**.

More information

Attribute	Description
Configuration name	*glide.ui.magellan.favorites.allow_public*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 4.3 • CVSS rating: Medium

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Security risk details: Unauthenticated users are allowed to access and potentially manipulate the Favorites of the shared "Guest" user, increasing the risk of unauthorized UI customization, data exposure, and user interface misuse.
Functional impact	Enabling this property acts as a layer of protection from unauthorized users.
Dependencies and prerequisites	None

Enable CRL-based certificate revocation checking for outbound HTTP requests

Use the *com.glide.communications.httpclient.disable_crl_check* property to control Certificate Revocation List (CRL) revocation checking for outbound HTTP requests over Transport Layer Security (TLS).

When the *com.glide.communications.httpclient.disable_crl_check* property is set to `false`, CRL checking remains available as a revocation-check mechanism. Outbound HTTP requests over TLS that connect to hosts whose certificates only provide a CRL distribution point have their certificate checked against that CRL before the connection proceeds.

When set to `true`, CRL checking is never performed, regardless of whether a certificate provides a CRL distribution point. The platform relies solely on Online Certificate Status Protocol (OCSP) for revocation checking.

To configure this property:

1. Navigate to `/sys_properties_list.do` on the instance.
2. Set the *com.glide.communications.httpclient.disable_crl_check* property to `false`.

More information

Attribute	Description
Configuration name	*com.glide.communications.httpclient.disable_crl_ch*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Architecture, design, and threat modeling
Security risk	• Security risk rating: High • CVSS score: 7.5 • Security risk details:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	When set to `true`, certificates that only provide a CRL distribution point (and no OCSP responder) are never checked for revocation. Certificates encountering an OCSP processing error can't fall back to a CRL-based check. The platform can establish outbound HTTPS connections to hosts with revoked certificates. This results in loss of authentication and possible loss of confidentiality.
Functional impact	When set to `false`, certificates with only a CRL distribution point are checked against the CRL before the outbound TLS connection proceeds. If the certificate authority's CRL endpoint can't be reached, the platform's handling is governed by the *com.glide.communications.httpclient.fail_on_non_pa* property.
Dependencies and prerequisites	The *com.glide.communications.httpclient.disable_crl_ch* property has no effect unless the *com.glide.communications.httpclient.verify_revoked* property, the overall gate for certificate revocation checking, is set to `true`. The *com.glide.communications.httpclient.disable_crl_ch* property interacts with the *com.glide.communications.httpclient.fail_on_non_pa* property: • When *com.glide.communications.httpclient.disable_crl_* is set to `true`, the *fail_on_non_pass_crl_status* property has no effect, since CRL checking is never performed. • When *com.glide.communications.httpclient.disable_crl_* is set to `false`, the *fail_on_non_pass_crl_status* property determines whether the platform terminates connections when CRL checks can't determine revocation status.

Enforce CRL certificate revocation checking for outbound HTTP requests

Use the *com.glide.communications.httpclient.fail_on_non_pass_crl_status*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

property to control whether the platform terminates outbound HTTP requests when Certificate Revocation List (CRL) checks can't determine revocation status.

The ability to verify certificate revocation status strengthens the authentication process. However, revocation checks are out-of-band requests to a certificate authority's revocation endpoint. Network failures, DNS resolution issues, or unavailable revocation services may cause the check to fail and halt outbound HTTP requests, creating a potential denial-of-service condition. The denial-of-service risk is mitigated by caching of revocation check results.

Two main approaches check certificate revocation status: Certificate Revocation Lists (CRLs) and Online Certificate Status Protocol (OCSP).

When the *com.glide.communications.httpclient.fail_on_non_pass_crl_status* property is set to `false` and the CRL check can't determine revocation status, the platform continues with remaining certificate validations (hostname, expiration, signature, certificate chain).

When set to `true` and the CRL check can't determine revocation status, the platform either terminates the connection or falls back to OCSP revocation checking. If OCSP is also unable to determine revocation status, the connection is terminated.

To configure this property:

1. Navigate to `/sys_properties_list.do` on the instance.
2. Set the *com.glide.communications.httpclient.fail_on_non_pass_crl_status* property to `true`.

More information

Attribute	Description
Configuration name	*com.glide.communications.httpclient.fail_on_non_pa*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 2.3 • CVSS rating: Low • Security risk details: Outbound HTTP requests that rely on TLS certificate validation for the remote hosts may be impacted if the CRL revocation check can't be completed. The platform may connect to remote hosts with revoked certificates, leading to a loss in authentication and possible loss in confidentiality.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	The *com.glide.communications.httpclient.fail_on_non_pa* property affects any platform functionality that makes outbound HTTP requests over TLS, for example Integration Hub or Outbound Web Services. When set to `false`, if CRL can't determine the revocation status, the platform verifies the next certificate in the chain and allows the connection with the remote host.
Dependencies and prerequisites	The *com.glide.communications.httpclient.fail_on_non_pa* property interacts with the *com.glide.communications.httpclient.disable_crl_ch* property. • If the *com.glide.communications.httpclient.disable_crl_* property is set to `false` and the *com.glide.communications.httpclient.fail_on_non_* property is set to `true`, the platform will perform the CRL revocation check for the certificate. • If the *com.glide.communications.httpclient.disable_crl_* property is set to `true`, then the *com.glide.communications.httpclient.fail_on_non_* property value will not have any effect. The platform will perform the OCSP revocation check for the certificate.

Enforce domain access control on all tables

The *glide.sys.domain.access_handler.included_tables* property controls which tables have cross-domain write protection enforced.

When set to `*` (wildcard), all tables receive cross-domain write protection. When set to a comma-separated list of specific table names, only those tables have cross-domain write protection enforced. When left empty, no tables receive cross-domain write protection, disabling the feature.

1. Navigate to /sys_properties_list.do on the instance.
2. Verify the *glide.sys.domain.access_handler.included_tables* property exists in the `sys_properties` table and is set to `*`.

More information

Attribute	Description
Configuration name	*glide.sys.domain.access_handler.included_tables*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	`*`
Default value	`*`
Fallback value	Empty
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 5.6 • Common Vulnerability Scoring System (CVSS) rating: Medium • Security risk details: If *`glide.sys.domain.access_handler.included_tables`* is narrowed to a subset of tables, emptied, or if the default configuration is removed, domain boundary enforcement stops. The instance no longer enforces domain boundaries on the affected tables. In a domain-separated (multi-tenant) instance, users in one domain can create or update records with a `sys_domain` value outside their assigned domain. This breaks the tenant isolation that domain separation provides, resulting in unauthorized cross-domain data exposure and data planting.
Functional impact	The *`glide.sys.domain.access_handler.included_tables`* property controls the scope of domain access handler enforcement across tables in the instance. Modifying the value changes which tables receive cross-domain write protection. Expanding the property value toward `*` (wildcard) increases the scope of domain access handler enforcement. More tables undergo record visibility and access evaluation for domain boundaries. This can affect how users, integrations, and background operations interact with domain-separated data, potentially blocking writes that were previously allowed on tables outside the enforcement scope. Configuration options: • `*` (wildcard) – Enforce domain access handler on all domain-applicable tables • Comma-separated table list – Enforce domain access handler only on the specified tables • Empty or absent – Enforce domain access handler on no tables (enforcement turned off)
Dependencies and prerequisites	This property is only evaluated when the Domain Support (`com.glide.domain`) plugin is active.

Enforce field ACLs for inbound query requests

Manage how incoming queries are validated on your instance.

Use the *glide.export.query.enforce_field_acl* property to control whether field-level ACLs are enforced on the fields referenced in an inbound query requests. When set to **true**, field ACLs are checked against fields used in the incoming query, and the query is rejected if the user is unauthorized to access those fields. When set to **false**, field ACLs are not checked on query conditions, and the query executes regardless of field-level access restrictions.

This property applies only to field ACL enforcement on query conditions. Setting this property to **false** does not affect whether users can read field values they are not otherwise authorized to view. Field-level read ACLs remain enforced regardless of this setting.

Set the property *glide.export.query.enforce_field_acl* to **true**.

More information

Attribute	Description
Configuration name	*glide.export.query.enforce_field_acl*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 4.4 • CVSS score: Medium • Security risk details: This can result in information disclosure to unauthorized parties.
Dependencies and prerequisites	None

Enforce read ACLs on report views

Manage how Read ACLs are enforced on your instance.

The property *glide.report.report_view.read_acl*, when set to **enforce**, enforces the read ACL (table level) on reporting functions when there is no Report View ACL on the table/field.

Ensure the property *glide.report.report_view.read_acl* is set to **enforce**.

Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	enforce
Default value	enforce
Fallback value	enforce
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 7.1 • CVSS rating: High • Security risk details: ACLs could be bypassed, leading to potential sensitive information disclosure.
Functional impact	None
Dependencies and prerequisites	None

Enable Anti-CSRF Token for Userperf

Use a system property to ensure CSRF (Cross-Site Request Forgery) protection is enforced when setting user preferences.

Use the *glide.security.userpref_csrf_check.enable* system property to enforce CSRF (Cross-Site Request Forgery) protection when setting user preferences to the User Preference Definitions [sys_user_preference_definition] table via URI parameters. If the property isn't set to the recommended value of `true`, then the **CSRF token required** flag is overridden when set on individual preferences, and preferences can be set via URI parameters without requiring a CSRF token.

Enforce Query ACLs for Knowledge Quick Links

Enforce query ACLs for Knowledge Quick Links using a system property.

When the *com.glide.security.query_acl.enabled.knowledge_quick_links* system property is set to **true**, query ACLs are enforced for Knowledge Quick Links. If this property is set to **false**, an attacker can use blind queries to enumerate and exfiltrate data due to the default behavior of `GlideRecord.addEncodedQuery`.

If the property doesn't exist in the System properties [sys_properties] table, the secure default of **true** is used. A third option, **external_and_guests** enforces query ACLs only for external users and guests.

Verify that the *com.glide.security.query_acl.enabled.knowledge_quick_links* system property is set to **true**.

More information

Attribute	Description
Configuration name	*com.glide.security.query_acl.enabled.knowledge_qu*

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Configuration type	System Properties (/sys_properties_list.do)
Data type	String - Used as a ternary operator
Recommended value	true
Default value	true
Fallback value	true
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 5.3 • CVSS score: Medium • Security Risk: ACLs can be bypassed, disclosing field data to users who don't have permissions to see it. This disclosure could include sensitive data depending on the table exploited.
Functional impact	Users aren't able to perform specific queries on fields where they don't have field level access.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Enforce Query ACLs for SubLists, List Counts and Widget Data Tables

Enforce query ACLs on sublist, list count, and widget data table queries using system properties.

Set *com.glide.security.query_acl.enabled.sub_lists* to **true** to enforce query ACLs on sublist queries, such as grouped lists and related lists.

Set *com.glide.security.query_acl.enabled.list_count* to **true** to enforce query ACLs on list count queries.

Set *glide.security.query_acl.enabled.data_table* to **true** to enforce query ACLs on widget data tables.

If any of these system properties are set to **false**, an attacker can use blind queries to enumerate and exfiltrate data due to the default behavior of `GlideRecord.addEncodedQuery`. If these properties don't exist in the System Properties [sys_properties] table, the secure default of true is used. A third option, *external_and_guests*, enforces ACLs only for external users and guests.

Ensure these system properties do not appear in the System Properties [sys_properties] table or are set to **true**.

Dependencies and prerequisites	None

Enforce valid query string choice [New in Security Center 7.0]

Use a system property to ensure that any choice field value, when passed via a URL query string, is a valid active choice when a record is created.

When the *glide.ui.query_string.enforce_valid_choice_on_create* system property is set to **true**, the platform validates that any choice field value passed via a URL query string (for example, from a list filter) is a valid active choice when the record is created.

If invalid, the value is ignored and the field falls back to its default value. When the property is **false**, validation is inactive, and the system accepts any value, even invalid or inactive ones. This acceptance can potentially result in incorrect or unexpected data being stored on records.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Ensure *glide.ui.query_string.enforce_valid_choice_on_create* exists in the System Properties [sys_properties] table and is set to **true**. If the property doesn't exist in the table, the fallback value is **false**.

More information

Attribute	Description
Configuration name	*glide.ui.query_string.enforce_valid_choice_on_crea*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	true
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 2.2 • CVSS score: Low • Security Risk: Set this property to **true** to ensure that only valid choices are used for new record creation. Invalid choices may lead to minor and unexpected data integrity issues, where a user is able to select an unintended value.
Functional impact	Existing instances and workflows may rely on new records being created based on a filter that contains an invalid or inactive choice. Use the following process to observe this behavior: **1.** Log in to an instance as an admin user. **2.** Create a String field on any table. For example, an incident with 2 choices: **Test1** and **Test2**. **3.** Create a list filter on incident table selecting the string field with value set to **Test2**. **4.** Go to dictionary field and deactivate the choice **Test2**. **5.** Go to the filter selected in step 3 and select **New** button. **6.** Check the value of the String type field in the newly opened record. When the property is set to **true**, the string field shouldn't have a value or should show the default value. When the property is set to **false** (default), the string field has the value set to **Test2**.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Ensure An Instance is Allowed to Connect to Only Trusted IP Addresses

Use a system property to define a list of IP ranges that are appended to the outbound IP allow list.

Use the *glide.custom.ip.outbound.authenticate.allow* system property to define a list of IP ranges that are appended to the outbound IP allow list of an instance. The property value contains a comma separated range of IP addresses in IPv4 or IPv6 format. IP ranges are specified using a hyphen (10.0.10.14-10.0.10.19), using CIDR notation (10.0.10.0/24), or consist of a single IP address (10.0.10.5). The instance is allowed to connect to the IP ranges in this property, unless listed in the IP deny list.

Note: IP ranges in this property are appended to the outbound IP allow list regardless of the value of the *glide.ip.authenticate.strict* property. The IP Address Access Controls [ip_access] table provides an equivalent option to add to both the inbound/outbound allow/deny IP lists of an instance. Refer to the Steps to Configure section in IP range based authentication.

Ensure that the *glide.custom.ip.outbound.authenticate.allow* system property value is either an empty, or a comma-separated list containing only trusted IP ranges that your want to allow your instance to access.

More information

Attribute	Description
Configuration name	*glide.custom.ip.outbound.authenticate.allow*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	Empty, or a comma-separated list containing only trusted IP ranges that your want to allow your instance to access.
Default value	None
Fallback value	None
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: If IP ranges are added to the property, it increases the risk of that an instance may connect to unauthorized or non-essential external services that should otherwise be blocked. This can weaken network-level security. In cases where additional IP ranges are necessary, be careful to include a minimal set of only trusted IPs.
Functional impact	There should be no functional impact. It can only be used to increase your instance's access.
Dependencies and prerequisites	None

Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details:
Functional impact	None
Dependencies and prerequisites	None

For Self-Hosted Instance, Ensure only Trusted IP Addresses are Allowed to Connect to An Instance

Use system properties to control which inbound IP addresses can connect to self-hosted instances.

A self-hosted instance is a customer-managed deployment of the ServiceNow platform, which runs on your own infrastructure instead of ServiceNow's cloud. A instance is classified as self-hosted if the property *glide.installation.self_hosted* is set to true.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

On these self-hosted instances, the *glide.ip.authenticate.allow.self_hosted_enabled* system property overrides the inbound IP allow list for an instance when set to true. The *glide.ip.authenticate.allow.secured.self_hosted_enabled* system property provides the same functionality in strict mode. Strict mode is enabled when the system property *glide.ip.authenticate.strict* property is set to true.

In strict mode

The *glide.ip.authenticate.allow.secured.self_hosted_enabled* property replaces the inbound IP allow list with the IP allow list defined in the property *glide.ip.authenticate.allow.secured.self_hosted_list*.

Not in strict mode

The *glide.ip.authenticate.allow.self_hosted_enabled* property replaces the inbound IP allow list with the IP allow list defined in the *glide.ip.authenticate.allow.self_hosted_list* property.

All list properties mentioned are strings containing lists of IP ranges that are appended to the inbound IP allow list of an instance. The strings contain a comma separated range of IP addresses in IPv4 or IPv6 format. IP ranges can be specified using a hyphen (10.0.10.14-10.0.10.19), using CIDR notation (10.0.10.0/24), or consist of a single IP address (10.0.10.5).

Note: Both of the list properties have a default value of `127.0.0.1` if not set. IP ranges of the property *glide.custom.ip.authenticate.allow* are always appended to the inbound IP allow list, and are not affected by the properties described here. The IP Address Access Controls [ip_access] table is not affected by these properties.

If your instance is self-hosted:

1. Set the *glide.ip.authenticate.allow.self_hosted_enabled* and *glide.ip.authenticate.allow.secured.self_hosted_enabled* properties to `true`.
2. Ensure that the *glide.ip.authenticate.allow.secured.self_hosted_list* and *glide.ip.authenticate.allow.self_hosted_list* system properties are either not set, or contain a comma-separated value consisting of only trusted IP ranges that you want to allow access to your instance.

More information

Attribute	Description
Configuration name	• *glide.ip.authenticate.allow.self_hosted_enabled* • *glide.ip.authenticate.allow.secured.self_hosted_* • *glide.ip.authenticate.allow.secured.self_hosted_* • *glide.ip.authenticate.allow.self_hosted_list*
Configuration type	System Properties (/sys_properties_list.do)
Data type	• Boolean • Boolean

Attribute	Description
	• String • String
Recommended value	**For self-hosted instances** • `true` • `true` • empty, or a comma-separated list of trusted IP ranges • empty, or a comma-separated list of trusted IP ranges **For ServiceNow hosted instances** • `false` • `false` • `127.0.0.1` • `127.0.0.1`
Default value	• `false` • `false` • `127.0.0.1` • `127.0.0.1`
Fallback value	• `false` • `false` • `127.0.0.1` • `127.0.0.1`
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: The default IP allow list for instances is geared towards allowing ServiceNow personnel and infrastructure access to an instance. If an instance is self-hosted, the default IP allow list increases the risk of unauthorized or non-essential access to the instance from IPs that should otherwise be blocked on self-hosted instances as these instance are generally not on the ServiceNow network. Setting the properties *`glide.ip.authenticate.allow.self_hosted_enabled`* and

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	*glide.ip.authenticate.allow.secured.self_hosted_* to `true` ensures only those IP addresses the instance owner explicitly allows are able to access an instance.
Functional impact	If your instance is self-hosted, there should be no unexpected functional impact from any of these properties as the instance is not on the ServiceNow network, and therefore does not have access to those IP ranges on the default IP allow list. If the instance is not self-hosted, setting these properties may break functionality.
Dependencies and prerequisites	None

Prevent disabling of data separation enforcement

Prevent bypassing Mosaic domain-visibility filtering to maintain data separation boundaries across business units and customer domains.

The *glide.one_extend.mosaic.sync.disable_data_separation_enforcement* property controls whether the platform's Mosaic domain-visibility filtering for data-separated instances is bypassed.

When set to `false` (the secure, default state), the platform continues to compute and enforce per-domain visibility grants whenever data separation is enabled. Domain-scoped users see only the records within their granted visibility roots and Mosaic consumers apply the same filtering.

When domain-visibility filtering is bypassed on an instance with data separation enabled, the platform stops computing which domains a user is permitted to see. Instead, the platform treats every domain as visible to all users.

More information

Attribute	Description
Configuration name	*glide.one_extend.mosaic.sync.disable_data_separation_enforcement*
Configuration type	System Properties (`/sys_properties_list.do`)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Data separation
Security risk	• Severity score: 5.4 • CVSS rating: Medium • Security risk details:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	When domain-visibility filtering is bypassed, users in one business unit or customer domain can access records belonging to another domain. Data becomes exposed across organizational boundaries that were designed to remain isolated. Failure to enforce this control may result in unauthorized cross-domain data disclosure and a breakdown of the data-separation guarantees an organization relies on for regulatory or contractual compliance.
Functional impact	When set to `false`, the platform preserves domain-visibility filtering for Mosaic sync consumers. Integrations that were relying on the broader, unfiltered view of cross-domain records will see records disappear from their results.
Dependencies and prerequisites	Only applicable when domain and data separation is configured (plugin *`com.glide.domain.msp_extensions.installer active`*).

Require authorization for data broker rest API

Use the *`glide.basicauth.required.databrokerrestapiprocessor`* property to require basic authorization for all inbound Data Broker Rest API requests.

If the *`glide.basicauth.required.databrokerrestapiprocessor`* system property is not set to the recommended value of **true**, then basic authorization is not required for all inbound Data Broker Rest API requests.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*`glide.basicauth.required.databrokerrestapiprocesso`*

Attribute	Description
Dependencies and prerequisites	None

Restricted Binding functionality in Case Bearer authorization

Restricted Binding Functionality in Case Bearer Authorization

Use the *glide.oauth.enforce_restricted_binding_for_ui* system property and enable restricted binding for an OAuth entity to prevent the access tokens generated by that entity from being used for UI calls (For example, `incident_list.do`).

When restricted binding is turned off, the access token generated can be used for UI calls regardless of the value of the system property.

When the *glide.oauth.enforce_restricted_binding_for_ui* system property isn't set to **true** or restricted binding is turned off, a user with the access token to access an API (for example, a mobile API) can obtain a session and use it to access other restricted resources on the instance (for example, `incident_list.do`).

Ensure that the *glide.oauth.enforce_restricted_binding_for_ui* property is set to **true**.

More information

Attribute	Description
Configuration name	*glide.oauth.enforce_restricted_binding_for_ui*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 5.0 • CVSS score: Medium • Security risk details: When the *glide.oauth.enforce_restricted_binding_for_ui* system property isn't set to **true**, a user with the access token to access an API (for example, a mobile API) can obtain a session and use it to access other restricted resources on the instance (for example, `incident_list.do`).
Functional impact	When the *glide.oauth.enforce_restricted_binding_for_ui* system property is set to **true** and restricted binding is enabled for a specific OAuth entity, the access token generated using that entity can't be used for UI calls (for example, `incident_list.do`).

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Dependencies and prerequisites	None

Deny by default with empty ACLs

Use the *glide.sm.default_mode* property to control the default behavior of security manager when it finds that existing Access Control List (ACL) rules are a part of wildcard table ACL rules.

Prevent your instance's legacy security manager from allowing access to resources when there are no ACLs defined for that resource, or if there are only wildcard table-level ACLs (for example, `incident.*`). When allowed access by default, anything that does not have explicit ACLs set is susceptible to manipulation.

Set the **glide.sm.default_mode** system property value to **deny** to disallow access when there are no define ACL rules, or there are only wildcard table-level ACLs.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.sm.default_mode*
Configuration type	System Properties (/sys_properties_list.do)
Category	Architecture, design, and threat modeling
Purpose	Best security practice would be to restrict an Access to the tables by an unauthorized user. • If there are no ACL rules in place for tables, this property ensures that at least wildcard ACLs are validated for any CRUD operation performed on the table/field. • These rules restrict the read, write, create, and delete operations on all tables, unless the user has the admin role or meets the requirements of another table ACL rule.
Recommended value	deny
Default value	deny
Functional impact	If you set this property to **Allow**, the wildcard table ACL rules allow CRUD operations on all tables unless there are specific table ACL rules in place to restrict such operations. **Note:** This plugin is not intended for existing instances, as it might modify security access to tables that are already in use in a production environment.
Security risk	6.3

Attribute	Description
References	Default deny property

To learn more about adding or creating a system property, see Add a system property.

Set automatic token cleanup for token credentials

Use the *com.snc.platform.security.token.auth.cleanup* property to ensure that expired API keys and HMAC secrets are deleted, thereby limiting the potential for token reuse.

If the *com.snc.platform.security.token.auth.cleanup* system property is set to the insecure value of **false**, expired API keys and HMAC secrets will not be deleted. This creates a potential for token reuse. If the token was expired due to leakage or compromise, reuse exposes the instance to anyone possessing the leaked token. Expired tokens are kept for the number of days defined by the *com.snc.platform.security.token.auth.days.expired.hmac_secret.is.kept* and *com.snc.platform.security.token.auth.days.expired.api_key.is.kept* system properties. Integer values of 0 and greater are valid values. A value of 0 causes the expired tokens to be deleted in the same day. The default of 7 days, or fewer, is recommended.

Ensure the property *com.snc.platform.security.token.auth.cleanup* doesn't exist in the System Properties [sys_properties] table or is set to **true**. Ensure that the properties *com.snc.platform.security.token.auth.days.expired.api_key.is.kept* and *com.snc.platform.security.token.auth.days.expired.hmac_secret.is.kept* don't exist in the System Properties [sys_properties] table or are set to 7 or less.

Attribute	Description
Fallback value	• true • 7 • 7
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 5.1 • CVSS score: Medium • Security risk details: A high number of days increases the exposure period for token reuse.
Dependencies and prerequisites	None

Authentication

The authentication category covers the main elements of modern authentication to confirm an entity and its claims are authentic and correct, resistant to impersonation and prevent interception of passwords.

The ASVS standard builds on the NIST 800-63b (https://pages.nist.gov/800-63-3/sp800-63b.html) specification for this section.

Authentication includes password policy, controls and storage, proper implementation of authenticators and proper implementation of out of band or one time verifiers.

Activate role-based multi-factor authentication [Updated in Security Center 1.3]

Use the *glide.authenticate.multifactor* property to enforce role-based multi-factor authentication (MFA) for all users assigned to specific roles.

Enforce multi-factor authentication based on the roles assigned to the user. If a user has been assigned "admin", "security_admin" or "user_admin" roles in the multi-factor roles list, MFA will be enforced.

- Set this property to **true** to enforce role-based multi-factor authentication for all users assigned to specific roles.
- Set this property to **false** to disable role-based multi-factor authentication for all users assigned to specific roles.

More information

Attribute	Description
Property name	*glide.authenticate.multifactor*
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Purpose	Enforce role-based multi-factor authentication for all users assigned to specific roles.
Type	true/false
Recommended value	*`true`*
Security Dependencies	Activate **Role based multi-factor authentication** within the **Multi-factor Criteria table**.
Security risk rating	7.2
Functional impact	Enabling this property improves the experience of the user. It acts as an extra layer of protection and security against compromised credentials.
Security risk	(Moderate) If this property is not enabled, there is a risk of unauthorized access to sensitive data.
References	Configure role-based multi-factor criteria

To learn more about adding or creating a system property, see Add a system property.

Activate role based multi-factor authentication

Use the *`glide.authenticate.multifactor`* property to enforce role-based multi-factor authentication (MFA) for all users assigned to specific roles.

The *`glide.authenticate.multifactor`* property enforces multi-factor authentication (MFA) based on the roles assigned to the user. When set to **true**, the platform enforces role-based MFA for all users whose roles are listed in the Multi-factor Criteria [multi_factor_criteria] table.

The Multi-factor Criteria [multi_factor_criteria] table defines which roles require MFA authentication. If a user has been assigned admin, security_admin or user_admin roles in the multi-factor roles list, MFA is enforced.

Enforcing MFA based on roles strengthens authentication security and aligns with best practices for protecting privileged accounts.

- Navigate to /sys_properties_list.do on the instance and verify that the *`glide.authenticate.multifactor`* property exists and is set to `true`.
- Navigate to `/multi_factor_criteria_list.do` on the instance and verify that the *`Role based multi-factor authentication`* record has **Active** set to **true**.

Attribute	Description
	authentication factor at login, and their password. Users without one of these roles are unaffected.
Dependencies and prerequisites	For role-based MFA enforcement to take effect, *glide.authenticate.multifactor* must be set to **true** and Multi-factor Criteria [multi_factor_criteria] must be active.

Anti-CSRF token (instance security hardening)

Use the *glide.security.use_csrf_token* property to ensure the use of a secure token to identify and validates incoming requests, which in turn are used to prevent these attacks.

Cross-Site Request Forgery (CSRF) is an attack that forces an end user to execute unwanted actions on a web application in which they're currently authenticated. CSRF attacks specifically target state-changing requests, not theft of data, since the attacker has no way to see the response to the forged request.

Note: By default, the *glide.security.use_csrf_token* property is set to `true` for zBoot instance.

The following properties can be enabled for added controls over CSRF token:

- *glide.security.csrf_previous.time_limit*
- *glide.security.csrf_previous.allow*
- *glide.security.csrf.strict.validation.mode*

More information

Attribute	Description
Property name	glide.security.use_csrf_token
Configuration type	System Properties (/sys_properties_list.do)
Configure in Instance Security Center	Yes
Purpose	To protect the application from potential CSRF attack.
Recommended value	true
Functional impact	(Low) This remediation enables an extra validation step before the instance user submits a write request to the instance. Every write request contains a CSRF token (i.e a validation/CSRF ID tied to the user session). When the user session expires, the secure token expires with it.
Security risk	(High) Cross Site Request Forgery is a significant security risk that violates the integrity of the instance data. An attacker can launch the CSRF attack by abusing the trust of an instance user. With the help of social engineering attacks, a user can submit a malformed request on behalf of the attacker on the instance.

To learn more about adding or creating a system property, see Add a system property.

Control lockout time for invalid password reset attempts

The *password_reset.request.max_attempt_window* property controls the number of minutes a user must wait to reset or change their password after exceeding the maximum number of unsuccessful attempts that is set with the *password_reset.request.max_attempt* property.

The *password_reset.request.max_attempt_window* system property defines the number of minutes a user must wait to reset or change their password after exceeding the maximum number of unsuccessful attempts that is set with the *password_reset.request.max_attempt* property.

Ensure that the property *password_reset.request.max_attempt_window* is set to 1440 or greater.

More information

Attribute	Description
Configuration name	*password_reset.request.max_attempt_window*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	An integer greater than or equal to 1440
Default value	1440
Fallback value	1440
Category	Authentication
Security risk	• Severity score: • CVSS rating: • Security risk details: A value too low increases the risk of successfully brute forcing a password as a greater number of password reset attempts can be made.
Functional impact	None
Dependencies and prerequisites	None

Disable creating users from incoming emails

Use the *glide.user.trusted_domain* property to specify the comma-separated list of trusted domains used in the creation of users from incoming emails.

An administrator can set the *glide.pop3readerjob.create_caller* system property to automatically create users from incoming emails. If set this property to the insecure value, the instance automatically creates users from incoming email. Each user created will have the same hardcoded default password which makes bypassing authentication through brute force easier.

Ensure that the *glide.pop3readerjob.create_caller* system property is set to **false**.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.pop3readerjob.create_caller*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Authentication
Security risk	• Severity score: 5.4 • CVSS rating: Medium • Security risk details: Allowing automatic user creation without strong password controls undermines authentication security and increases the likelihood of system compromise.
Functional impact	None
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Disable resource owner password credentials (ROPC) in OAuth 2 token grants [New in Security Center 7.0]

Prevent Resource Owner Password Credentials (ROPC) from granting OAuth 2 tokens.

By default, Resource Owner Password Credentials (ROPC) are allowed to grant OAuth 2 tokens on your instances when a client application directly requests an access token using a user name and password. When the *glide.oauth.inbound.ropc.grant_type.disabled* is set to **true**, ROPC is inactive and can't be used to grant OAuth 2 tokens.

Ensure that the *glide.oauth.inbound.ropc.grant_type.disabled* system property is set to **true**. If the property doesn't exist on the System Properties [sys_properties] table, the default value is **false**. If this property exists on that table, it defaults to **false**.

More information

Attribute	Description
Configuration name	*glide.oauth.inbound.ropc.grant_type.disabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Fallback value	false
Category	Authentication
Security risk	• Severity score: 3.3 • CVSS score: Low • When the property is set to **false**, using ROPC to grant OAuth 2 tokens is allowed. ROPC is considered less secure that other authentication flows because the user's credentials are exposed to the application. This can lead to vulnerabilities in situations where the client is compromised and suffers from weaknesses similar to those of basic auth. OAuth 2.1 has deprecated ROPC.
Functional impact	When the property is set to **true**, ROPC is inactive and cannot be used to grant OAuth 2 tokens. This prevents any applications that are accessing the platform by granting OAuth 2 token using ROPC.
Dependencies and prerequisites	The OAuth 2.0 (com.snc.platform.security.oauth) plugin must be active.

To learn more about adding or creating a system property, see Add a system property.

Do not apply password policy at login [Updated in Security Center 1.5 and removed in 2.0]

Manage how password complexity is handled in your instance.

By setting the property *glide.apply.password_policy.on_login* to false there will be no password complexity enforcement at login time. Setting the property to true will enforce password complexity and lead to organization policy compliance issues.

As per ASVS 4.03 v2.1.9 recommendations:

"Verify that there are no password composition rules limiting the type of characters permitted. There should be no requirement for upper or lower case or numbers or special characters. (C6)"

Instead of password complexity enforcement, ASVS recommendations are to enforce a minimum length of 12 characters for password length.

Refer to OWASP ASVS v4.0 Authentication.

More information

Attribute	Description
Configuration name	*glide.apply.password_policy.on_login*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Recommended value	false
Default value	false
Category	Authentication
Security risk	• Severity score: 4.4 • CVSS score: Medium • Security risk details: Setting this property to **true** could enforce password complexity and lead to organization compliance issues.
Dependencies and prerequisites	None

Enable account recovery

Use the *glide.sso.acr.enabled* property to manage the account recovery feature.

The *glide.sso.acr.enabled* property controls whether the Account Recovery (ACR) feature is available on an instance configured for Single Sign-On (SSO) authentication. When set to the recommended value of **true**, the platform blocks turning on multi-SSO until account recovery is enabled. At least one user account is enrolled for it. It confines any session authenticated through the recovery path to writing only SSO and account-recovery-related configuration. This preserves a controlled, auditable path back into the system for users who lose access to their normal SSO credentials.

Verify that the property *glide.sso.acr.enabled* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.sso.acr.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Authentication
Security risk	• Severity score: 6.5 • CVSS rating: Medium • Security risk details: Without an account recovery path, a user who loses access to their normal sign-in method has no supported way back into the system. That gap commonly pushes administrators and help desks toward manual, ad hoc identity verification workarounds to restore access. Those workarounds are a well-known target for social engineering and account takeover because they bypass the

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	organization's standard authentication controls. Leaving a recovery path unavailable increases the risk of unauthorized account access and loss of control over who can regain entry to affected accounts.
Functional impact	Enabling this control doesn't disable SSO. It requires that an account-recovery path exist and restricts write access on a recovery-authenticated session to SSO- and recovery-related properties only. Admin users that have never configured account recovery, or that have zero users enrolled, are blocked from turning on Multi-SSO until at least one user opts in. Users may test the Multi-SSO activation flow and the account-recovery login flow when removing or disabling ACR-enrolled users.
Dependencies and prerequisites	SSO is enabled (the property *glide.authenticate.multisso.enabled* is set to `true`).

Enable basic authentication restriction

The *glide.authenticate.basic_auth.restriction.active* property controls whether the platform evaluates inbound basic-auth API requests against allowed access paths.

This property controls the Basic authentication restriction gate. This gate evaluates inbound basic-auth API requests (username + password) from interactive-login accounts. When set to `true`, the gate evaluates each request against allowed access paths. When set to `false`, every basic-auth API request bypasses evaluation.

Important: Set to `false` only as a temporary emergency measure—for example, to restore basic-auth access during an active security investigation. Revert to `true` as soon as the emergency resolves.

More information

Attribute	Description
Configuration name	*glide.authenticate.basic_auth.restriction.active*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Authentication
Security risk	• Severity score: 8.1 • CVSS rating: High • Security risk details: When set to `false`, accounts that authenticate interactively through the browser or service portal can

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	also authenticate to the API using only a username and password. This bypasses any multi-factor authentication that would otherwise be required for those accounts' interactive logins. This creates a credential-compromise attack path: an attacker who obtains a valid password through phishing, credential stuffing, or a prior breach can use it directly against the API without satisfying a second factor. Leaving this property set to false for an extended period removes multi-factor authentication (MFA) protection for every interactive-login account, substantially increasing the risk of account takeover.
Functional impact	When set to `true` for the first time, the basic authentication restriction starts in tracking mode. Basic-auth requests are recorded (not restricted) in the exception table (sys_user_basic_auth_exception) for admin review. Actual restriction begins once the separate enforcement mechanism activates, at which point users who don't qualify under an allowed access path are denied access. If this property was previously set to `false` after enforcement began, setting it back to `true` resumes enforcement immediately. Tracking mode doesn't start. Before enforcement begins, administrators must review the exception table. Set an appropriate decision for each listed account. Convert integration accounts to Web Service Access Only where possible. Setting this property to `false` after enforcement has begun immediately restores unrestricted basic-auth access for every account including previously-restricted accounts. Set it back to `true` as soon as any investigation is complete.
Dependencies and prerequisites	The *`com.snc.integration.multifactor.authentication`* plugin must be active.

Enable CAPTCHA for customer registration

Reduce the risk of requests by malicious bots by enabling CAPTCHA for customer registration.

The *`sn_customerservice.captchaEnabled`* system property determines if CAPTCHA validation is tuned on or off for customer registration on the Customer Service Management Portal.

Set the system property **sn_customerservice.captchaEnabled** to **true** to enable CAPTCHA validation. If the property isn’t on the System Properties [sys_properties] table, the default value is **true**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*sn_customerservice.captchaEnabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Authentication
Security risk	• Severity score: 3.7 • CVSS rating: Low • Security risk details: CAPTCHA validation is considered a general guidelines to prevent potentially malicious bots from automatically submitting requests against an application.
Functional impact	Registering users may have a negative experience from having to pass the CAPTCHA validation.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Enable a deny-list password validation check

Manage the deny-list passwords in the Excluded Password table.

Use the *glide.enable.blacklist_password* property to monitor deny-list passwords. When the property is set to `true`, the user's password is checked against a specific list of deny-listed passwords. This denial prevents users from using a password from a set of breached passwords. You can maintain the list by inserting passwords into the Excluded Password [blacklisted_password] table. ServiceNow provides a small, medium, or large password list that can be inserted to the Excluded Password table through the UI page found at **All** > **Password Policy** > **Exclusion List Management**. ServiceNow installs the small list of 5,000 passwords to new instances.

Ensure that the *glide.enable.blacklist_password* system property is set to `true` and that the Excluded Password [blacklisted_password] table contains a minimum of 5,000 records.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	• *glide.enable.blacklist_password* system property • *Excluded Password [blacklisted_password]* table
Configuration type	• System Properties (/sys_properties_list.do) • Table record (/blacklisted_password_list.do)
Data type	• Boolean • Table record
Recommended value	• true • A minimum of 5,000 records
Default value	• true • ServiceNow provided list of 5,000 records
Fallback Value	• false • ServiceNow provided list of 5,000 records
Category	Authentication
Security risk	• Severity score: 5.9 • CVSS score: Medium • Security risk details: Attackers often target commonly used or previously exposed passwords. This can lead to account compromise through credential stuffing or brute-force attacks. Enforcing deny-listed password checks strengthens authentication security and reduces exposure to credential-based attacks.
Functional Impact	Some users may have difficulty selecting a password.
Dependencies and prerequisites	None
References	Exclude passwords through password policies on your instance

Enable CAPTCHA for external user registration

The *sn_ext_usr_reg.captchaEnabled* controls if CAPTCHA will be validated for external user registration.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

If the *sn_ext_usr_reg.captchaEnabled* system property is not set to the recommended value of **true**, then CAPTCHA isn't validated for external user registration and could lead to automatic account creation attacks.

Ensure that the property *sn_ext_usr_reg.captchaEnabled* is set to **true**.

More information

Attribute	Description
Configuration name	*sn_ext_usr_reg.captchaEnabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Authentication
Security risk	• Severity score: 3.7 • CVSS rating: Low • Security risk details: Enforcing CAPTCHA is critical to prevent bot-driven attacks and maintain the integrity of user onboarding.
Functional impact	None
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Enable CAPTCHA in password reset

Use the *password_reset.captcha.ignore* property to enable or disable requiring a CAPTCHA challenge when a user resets their password.

If the *password_reset.captcha.ignore* system property is not set to the recommended value of **false**, then a CAPTCHA challenge-response will not be used during the password reset process. CAPTCHAs help prevent automation attacks by prompting the user for a challenge-response that is not easily answered by automated systems.

Ensure that the property *password_reset.captcha.ignore* is set to **false**.

Note: This property is used for password reset automation only.

More information

Attribute	Description
Configuration name	*password_reset.captcha.ignore*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Authentication
Security risk	• Severity score: 5.6 • CVSS rating: Medium • Security risk details: If the CAPTCHA is disabled, an attacker may be more successful during automated attacks against the password reset feature.
Functional impact	None
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Disable email OTP for multi-factor authentication

Manage how two-factor authentication is applied on your instance.

The *glide.authenticate.multifactor.email.otp.enabled* property controls whether a token for the second authentication factor can be sent via email. Email is considered a weak multi-factor authentication (MFA) factor which an attacker is more likely to gain access into for defeating MFA.

If the property is set to **false**, the user doesn't see the email OTP option on the MFA validation screen.

If the property is **true**:

- The email factor is shown in cases where the email factor policy is inactive and no other 2fa registered.
- The email factor is shown if the email factor policy is active and evaluated to **true**.
- The email factor is not shown if the email factor policy is active and evaluated to **false**.

More information

Attribute	Description
Configuration name	*glide.authenticate.multifactor.email.otp.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	true
Category	Authentication

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 3.1 • CVSS score: Low • Security risk details: An attacker may successfully bypass MFA when they have the user's password.
Functional impact	Users who rely solely on the email one time passcode as their multi-factor authentication method will no longer see that option on the MFA validation screen. They must enroll an alternative factor such as an authenticator app, a hardware security key, or SMS before this property is turned off, otherwise they may be unable to complete login until an administrator enrolls an alternative factor for them.
Dependencies and prerequisites	None
References	Email as an MFA factor

Enable password reset policy checks

Use the **glide.enable.password_policy** property to enable password policy checks whenever a user changes their password using the user interface.

Use the **glide.enable.password_policy** property to customize password strength validation rules for the Change Password form. Customize the length and complexity values to match your organization's security policy. If **glide.enable.password_policy** is not set to the recommended value of **true**, then password standards will not be enforced.

Ensure that the *glide.enable.password_policy* system property exists in the System Properties [sys_properties] table and is set to the value **true**. If the property does not appear in the System Properties [sys_properties] table, add a new record.

Important: The **glide.enable.password_policy** does not apply when an administrator changes a password or adds a user through script.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.enable.password_policy*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Authentication

Attribute	Description
Security risk	• Severity score: 7.4 • CVSS rating: High • Security risk details: Enforcing password complexity is critical to maintaining strong authentication and reducing exposure to account takeover.
Functional impact	None
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Enable relay state in SAML requests to prevent replay attacks

Reduce the risk of replay attacks by enabling relay state in SAML requests to help prevent replay attacks.

Protect against SAML replay attacks using the **glide.authenticate.sso.saml2.enable_relay_state_with_id** system property. When this property is set to **true**, the relay state parameter contains the sys_id of a record in the MultiSSO Request Parameters [multisso_request_parameter] table, which the relay state URL redirects to.

Set the system property **glide.authenticate.sso.saml2.enable_relay_state_with_id** to **true**. This helps prevent attackers who have gained access to a SAML request from accessing your instance by resubmitting a valid request.

More information

Attribute	Description
Technical configuration name	glide.authenticate.sso.saml2.enable_relay_state_with_id
Plugin applicability	Multi-Provider SSO plugin (com.snc.integration.sso.multi.installer)
Security risk	The relay state enabled by this system property helps protect your instance against replay attacks. Enabling the property helps prevent attackers who have gained access to a SAML request from accessing your instance by resubmitting a valid request.
Common Vulnerability Scoring System (CVSS) score	3.8
Common Vulnerability Scoring System (CVSS) rating	Low
Functional impact	When this property is set to true, the relay state in a SAML request contains the sys_id of a record in the MultiSSO Request Parameters [multisso_request_parameter] table, which contains relay state URL to redirect to.
Dependencies and prerequisites	None

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	Boolean
Base system value	true
Fallback value	false
Recommended value	true

To learn more about adding or creating a system property, see Add a system property.

Enable SMS code notification for enrollment and verification

The *password_reset.sms.use_notify* property controls the usage of SMS code notifications for password reset.

The *password_reset.sms.use_notify* system property controls usage SMS code notification for enrollment and verification. If *password_reset.sms.use_notify* is set to the recommended value **true**, then user isn't notified for password reset for SMS verification method and new device enrollment. Using SMS code notification for enrollment and verification is more secure that default email notification.

Ensure the property *password_reset.sms.use_notify* is set to **true**.

More information

Attribute	Description
Configuration name	*password_reset.sms.use_notify*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	TRUE
Fallback value	true
Category	Authentication
Security risk	• Severity score: 3.7 • CVSS rating: Low • Security risk details: Email-based notifications are generally less secure because they are more susceptible to account compromise and phishing attacks. Using SMS for verification provides stronger assurance of user identity and reduces the risk of unauthorized password resets or fraudulent device enrollments.
Functional impact	None
Dependencies and prerequisites	None

Enable SSL in LDAP authentication [Updated in Security Center 1.5 and 2.0]

Manage the encryption of LDAP authentication requests on your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Use the *glide.ldap.use.ssl* property to enable or disable TLS encryption for LDAP authentication requests sent over the network. If this property is not set to the recommended value of **true**, LDAP authentication is susceptible to a man-in-the-middle attack.

More information

Attribute	Description
Configuration name	*glide.ldap.use.ssl*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Authentication
Security risk	• Severity score: 8.1 • CVSS score: High • Security risk details: Setting this property to **false**, makes LDAP authentication vulnerable to a man-in-the-middle attack.
Dependencies and prerequisites	None
References	Lightweight Directory Access Protocol integration

Enforce current password policy compliance requirements on login

Reduce the risk of brute force account login by enforcing current password policy compliance requirements on login.

Help prevent interactive users from logging in to the instance with passwords that don't meet current administrator requirements using the **glide.apply.password_policy.on_login** system property.

Set the **glide.apply.password_policy.on_login** system property to **true** to enforce current password policy compliance requirements. If this property doesn't exist on the System Properties [sys_properties] table, the default value is **false**.

More information

Attribute	Description
Technical configuration name	glide.apply.password_policy.on_login
Plugin applicability	None
Security risk	Interactive users may continue to log in to the instance with passwords that don't meet current administrator requirements. This may mean that the users have weak passwords that don't meet up-to-date security requirements, potentially leading to an increased risk of brute-force account logins by a malicious user.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Common Vulnerability Scoring System (CVSS) score	4.4
Common Vulnerability Scoring System (CVSS) rating	Medium
Functional impact	If the existing passwords aren't in compliance with your current password policy, enabling this property forces users to change the passwords during their next login. This property is automatically set to **false**. Setting the value to **true** enforces a password policy during login. **Note:** Enabling this property might force a significant number of users who aren't in compliance with the new password policy to change their passwords.
Dependencies and prerequisites	None
Data type	Boolean
Base system value	false
Fallback value	false
Recommended value	true

To learn more about adding or creating a system property, see Add a system property.

Enforce device encryption and passcode requirements [New in Security Center 1.3]

The *glide.sg.device_encryption_enabled* property enforces the Federal Information Processing Standard (FIPS 140-2) Encryption. Mobile device encryption and passcode ensure that an unauthorized user can't access the content of a device even if the device is physically obtained.

When the *glide.sg.device_encryption_enabled* system property is set to **true**, the ServiceNow mobile app checks that device encryption is enabled and that device passcode is enabled. If encryption or passcode is not enabled, the user will not be allowed to log into the instance on mobile. This property enforces FIPS 140-2 Encryption. Mobile device encryption and passcode are important security features for ensuring an unauthorized user cannot access the content of the device even if the device is physically obtained.

Set the *glide.sg.device_encryption_enabled* system property to **true**.

More information

Attribute	Description
Configuration name	*glide.sg.device_encryption_enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Default value	FALSE
Category	Authentication
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: This creates a risk that sensitive data stored or accessed through the mobile app could be exposed if the device is lost, stolen, or compromised. Without encryption and passcode enforcement, unauthorized users can gain physical access to confidential information, undermining compliance with FIPS 140-2 and weakening overall data protection.
Dependencies and prerequisites	None
Functional impact	When this property is set to true, the mobile app will verify if device encryption is enabled. If encryption is not enabled, users will not be allowed to log into the current instance on mobile. Users are logged out and see the following warning message, suggesting that they set a device pin or encrypt the device and to try to login again. `You were logged out` `You need a passcode in order to use this instance on this device. Go to your device's settings to set one up`

Limit basic authentication restriction allowed roles

The *glide.authenticate.basic_auth.allowed_roles* property defines roles that bypass the Basic Authentication Restriction gate without multi-factor authentication.

This system property contains a comma-separated list of role names exempt from the Basic authentication restriction gate. When restriction is active, any interactive-login user holding one of the listed roles can authenticate through Basic Auth without multi-factor authentication or time-based one-time password. This role check runs unconditionally, before enforcement-date tracking logic and before any per-account review in the Basic Auth Exception table. A role match is never logged as a tracked exception and always bypasses the gate regardless of whether enforcement is enabled.

The out-of-box value is the single, dedicated role *snc_basic_auth_api_access*. Management, Instrumentation, and Discovery (MID) Server accounts pass this check without being separately listed. The *mid_server* role inherits *snc_basic_auth_api_access* through the platform role hierarchy, so a MID Server account transitively holds the allowed role without appearing in this property value.

To configure this property:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

1. Navigate to `/sys_properties_list.do` on the instance.
2. Ensure the *glide.authenticate.basic_auth.allowed_roles* property is limited to snc_basic_auth_api_access or another narrowly-scoped, dedicated integration role. Remove any broadly-held role such as admin, itil, or snc_internal.

More information

Attribute	Description
Configuration name	*glide.authenticate.basic_auth.allowed_roles*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String (comma-delimited list)
Recommended value	*snc_basic_auth_api_access*
Default value	*snc_basic_auth_api_access*
Fallback value	<None>
Category	Authentication
Security risk	• Severity score: 8.1 • CVSS score: High • Security risk details: If this property includes a widely-held role such as *admin*, *itil*, or *snc_internal*, every user holding that role receives a permanent, unconditional bypass of the Basic Authentication Restriction gate. This is not a temporary tracking-mode allowance. Unlike a per-account exception, which is logged and individually reviewed, role-based matches are never logged and never reviewed. An over-broad role grants silent, undetectable multi-factor authentication bypass to every current and future holder of that role. An attacker who obtains a valid password through phishing, credential stuffing, or a prior breach authenticates directly against the API without satisfying a second factor. This exposure extends to the entire population holding the listed role.
Functional impact	This property takes effect for users not already allowed through an earlier checks. Earlier checks include WSAO accounts, oauth_token requests, an active TOTP or multi-factor authentication session, or the allowed_users list. Keep the value limited to *snc_basic_auth_api_access* or another narrowly-scoped, dedicated integration role. This does not affect MID Server accounts. The mid-server role holds *snc_basic_auth_api_access* through role containment, independent of this property literal value.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	Removing a role from this list doesn't immediately deny access. Affected users fall through the same tracking and review flow as any other basic-auth user. This review process provides a safety net before actual denial takes effect. Before narrowing or auditing this property, confirm that any role kept in the list is a dedicated integration or service role, not one held by ordinary interactive users.
Dependencies and prerequisites	Plugin *com.snc.integration.multifactor.authentication* must be Active. No effect unless *glide.authenticate.basic_auth.restriction.active* is **true**.

Limit basic authentication restriction allowed users

The *glide.authenticate.basic_auth.allowed_users* property defines specific user accounts that bypass the Basic Authentication Restriction gate without multi-factor authentication.

This system property contains a comma-separated list of user sys_ids exempt from the Basic authentication restriction gate. When restriction is active, any interactive-login user whose sys_id appears in this list can authenticate through Basic Auth without multi-factor authentication or time-based one-time password. This user check runs unconditionally, before enforcement-date tracking logic and before any per-account review in the Basic Auth Exception table. A user match is never logged as a tracked exception and always bypasses the gate regardless of whether enforcement is enabled.

The out-of-box value is empty, so no account is exempted unless an administrator explicitly adds one. This property is intended for narrowly-scoped integration accounts that cannot satisfy multi-factor authentication requirements and do not hold a role listed in the allowed_roles property.

To configure this property:

1. Navigate to `/sys_properties_list.do` on the instance.
2. Ensure the *glide.authenticate.basic_auth.allowed_users* property contains only sys_ids for dedicated integration accounts with a documented business justification. Remove any account that no longer requires a standing MFA exemption for Basic Auth API access.

More information

Attribute	Description
Configuration name	*glide.authenticate.basic_auth.allowed_users*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String (comma-delimited list of sys_ids)
Recommended value	<Empty> or limited to specific, individually-reviewed dedicated service accounts
Default value	<Empty>

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Fallback value	<None>
Category	Authentication
Security risk	• Severity score: 8.1 • CVSS score: High • Security risk details: Any user sys_id added to this property receives a permanent, unconditional bypass of the Basic Authentication Restriction gate for that one account. This is not a temporary tracking-mode allowance. Unlike an account left to the default review flow, a listed sys_id is never logged and never subject to further review. That account permanently loses multi-factor authentication protection on its Basic Auth API access. An attacker who obtains that account's password through phishing, credential stuffing, or a prior breach can authenticate directly against the API without satisfying a second factor. Entries are added by sys_id rather than username. A stale entry can silently persist and continue exempting an account long after the original justification for adding it is gone. Nothing in the property's own value indicates which account it refers to.
Functional impact	This property takes effect for users not already allowed through an earlier check. Earlier checks include WSAO accounts, oauth_token requests, an active TOTP or multi-factor authentication session, or the allowed_roles list. Because this property ships empty, any populated entry is always a deliberate administrator action, never an inherited default. Removing a sys_id from this list does not deny that account access outright. Affected users fall through to the same allowed_roles check and enforcement-date tracking-mode review flow as any other basic-auth user. There is a review safety net before actual denial takes effect. Administrators should periodically re-validate every sys_id in this list against a live user record. Confirm each is still a legitimate, currently-needed integration account rather than a stale holdover. A bare sys_id gives no indication of which account it names.
Dependencies and prerequisites	Plugin *com.snc.integration.multifactor.authentication* must be Active. No effect unless *glide.authenticate.basic_auth.restriction.active* is **true**.

Limit Invalid Password Reset Attempts

The *password_reset.request.max_attempt* is used to control the maximum number of unsuccessful attempts that a user can reset or change their password before being locked out for a specified period of time.

The *password_reset.request.max_attempt* system property dictates the maximum number of unsuccessful password reset attempts that can be taken before the user is locked out of password reset process. The lockout period is determined by the value in *password_reset.request.max_attempt_window*.

Ensure that the property *password_reset.request.max_attempt* is set to 3 or less.

More information

Attribute	Description
Configuration name	*password_reset.request.max_attempt*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	An integer less than or equal to 3
Default value	3
Fallback value	3
Category	Configure Password Reset properties
Security risk	• Severity score: 7.5 • CVSS rating: High • Security risk details: If the value is too high, then it could be possible to perform brute force attack against password reset process.
Functional impact	None
Dependencies and prerequisites	None

Limit Allowed Number of Failed Login Attempts Before Lockout

Two script actions are available that enable a site administrator to manage the number of times a user can provide an incorrect password before being locked out from the ServiceNow AI Platform. You can enable either of these script actions to manage failed login attempts.

The *SNC User Lockout Check* or *SNC User Lockout Check with Auto Unlock* script actions enable the administrator to manage the number of failed login attempts for a user. Two script actions are available that enable a site administrator to manage the number of times a user can provide correct password before getting locked out from the Now Platform.

Additionally, the *glide.user.max_unlock_attempts* system property controls the number of allowed failed login attempts. If the value of *glide.user.max_unlock_attempts* is increased above the recommended value of 5, it increases the number of login attempts an attacker could make against a given user.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Ensure at least one of the script actions: *SNC User Lockout Check* or *SNC User Lockout Check with Auto Unlock* is enabled to manage failed login attempts. These script actions are stored in the Script Actions [sysevent_script_action] table.

Additionally, ensure the property *glide.user.max_unlock_attempts* is set to 5 or less.

More information

Attribute	Description
Configuration name	• *SNC User Lockout Check* (Script action) • *SNC User Lockout Check with Auto Unlock* (Script action) • *glide.user.max_unlock_attempts*(System property)
Configuration type	• Script Action (/sysevent_script_action.do) • System Properties (/sys_properties_list.do)
Data type	Integer (for system property)
Recommended value	• The Script Actions [sysevent_script_action] table has the record with sys_id `5e44f9bf0a0a0a0a019a6440b2137767` and/or the record with sys_id `d92636b2975301008e00958e3b297567` set to **active** • *glide.user.max_unlock_attempts* system property is set to an integer less than or equal to 5.
Default value	<none>
Fallback value	5 (for system property)
Category	Authentication
Security risk	• Severity score: 7.3 • CVSS rating: High • Security risk details: Allowing more attempts gives attackers additional opportunities to guess passwords, increasing the likelihood of unauthorized access and credential compromise. Proper lockout configuration is critical to maintaining strong authentication security.
Functional impact	None
Dependencies and prerequisites	None

Maximize failed login unlock timeout duration [Updated in Security Center 1.3]

A script action is available that enables site administrators to manage the number of times a user can provide an incorrect password before being locked out from the ServiceNow AI Platform. You can enable this script action to manage failed login attempts.

Help secure your instance against brute force attacks by defining a time period during which a user cannot attempt to log in after being locked out. The **glide.user.unlock_timeout_in_mins** system property unlocks the user account after the time period that is specified in it's value. If no value is specified, your instance unlocks the user account after the default period of 15 minutes.

Set the **glide.user.unlock_timeout_in_mins** system property value to a minimum of **15**. If **glide.user.unlock_timeout_in_mins** does not exist, the default lockout time is set to 15 minutes.

Ensure that the **SNC User Lockout Check with Auto Unlock** script action (found on the Script Action [sysevent_script_action] table) is present and active. The **SNC User Lockout Check with Auto Unlock** script action is installed with the High Security Settings (com.glide.high_security) plugin.

More information

Attribute	Description
Configuration name	• glide.user.unlock_timeout_in_mins (System Property) • sysevent_script_action (Script Action)
Configuration type	System Policy > Script Actions
Category	Authentication
Purpose	To enforce strict policy for failed login attempts to avoid brute forcing of credentials.
Recommended value	• **15** for the **glide.user.unlock_timeout_in_mins** system property • **Active** for the **SNC User Lockout Check with Auto Unlock** script action.
Functional impact	This remediation would enable administrator of the instance to monitor and report any malicious user access. No functionality impact, only User experience change.
Security risk	• Severity Score: 6.8 • Security Risk Details: If the property is not configured to a secure value and the lockout duration is not enabled, then it may be easier to brute force account logins in a faster time frame. This may allow a malicious user to eventually obtain unauthorized access to the instance. Impact on the instance will be limited to the privileged of the affected user login brute-forced.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Steps to configure

1. Navigate to **System Policy** > **Script Actions.**
2. Search for the name **SNC User*.
3. To enable management of failed login attempts, change the Active state of either the *SNC User Lockout Check with Auto Unlock* or *SNC User Lockout Check* scripts actions from **false** to **true**.
4. To reset the failed login counter after a successful login, you can activate the *SNC User Clear* script action.

Maximize reset password request retry window duration

The *password_reset.request.retry_window* property controls the number of minutes before the count for password reset attempts refreshes.

The *password_reset.request.retry_window* system property specifies the length of time before the count for password reset attempts refreshes.

Ensure that the property *password_reset.request.retry_window* is set to `1440` or more.

More information

Attribute	Description
Configuration name	*password_reset.request.retry_window*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	An integer greater than or equal to 1440
Default value	1440
Fallback value	1440
Category	Authentication
Security risk	• Severity score: 7.5 • CVSS rating: High • Security risk details: If the value is too low, then it will make brute forcing against password reset process attacks much faster.
Functional impact	None
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Maximize reset password request unlock window duration

The *password_reset.request.unlock_window* property controls the number of minutes a user must wait to start a reset request after the last successful unlock account action.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The *password_reset.request.unlock_window* system property controls the number of minutes a user must wait to start a reset request after the last successful unlock account.

Ensure the property *password_reset.request.unlock_window* is set to a value of `1440` or greater.

More information

Attribute	Description
Configuration name	*password_reset.request.unlock_window*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	An integer greater than or equal to 1440
Default value	1440
Fallback value	1440
Category	Authentication
Security risk	• Severity score: 5.9 • CVSS rating: Medium • Security risk details: If the value is too low, it increases the opportunity for a malicious actor from brute forcing the user's password using automated tools.
Functional impact	None
Dependencies and prerequisites	None

Maximize reset password SMS complexity

The *password_reset.sms.default_complexity* property controls the minimum required SMS code verification size required during password reset.

If the *password_reset.sms.default_complexity* system property isn't set to the recommended value of `6` or greater, then a weak SMS validation token is used.

Ensure the property *password_reset.sms.default_complexity* is set to `6` or more.

More information

Attribute	Description
Configuration name	*password_reset.sms.default_complexity*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	6 or higher
Default value	6
Fallback value	4

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Authentication
Security risk	• Severity score: • CVSS rating: • Security risk details: This increases the possibility of token guessing which could lead to account takeover.
Functional impact	None
Dependencies and prerequisites	None

Maximize reset password SMS pause window duration

Manage the time duration in minutes that a user must wait before they can request a new password reset code.

If the *password_reset.sms.pause_window* system property is not set to the recommended value of 2 minutes or greater, then a malicious user could initiate many password reset SMS codes in a brief window of time.

Ensure that the property *password_reset.sms.pause_window* is set to 2 or greater.

More information

Attribute	Description
Configuration name	*password_reset.sms.pause_window*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	2
Default value	2
Category	Authentication
Security risk	• Severity score: 4.8 • CVSS score: Medium • Security risk details: This increases the attacker's likelihood of predicting the SMS reset code.
Dependencies and prerequisites	None

Maximize reset password verification delay duration

Configure the delay, in milliseconds, that a user must wait before submitting a new password reset request.

If *password_reset.verification.delay* isn't set to the recommended value of 1000 or more, then password reset verification codes will be susceptible to brute force attacks.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*password_reset.verification.delay*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	An integer greater than or equal to 1000
Default value	1000
Fallback value	1000
Category	Authentication
Security risk	• Severity score: 5.9 • CVSS rating: Medium • Security risk details: The milliseconds delay limits the ability of a malicious actor to attempt to guess users identification or verification details, by using automation tools (bots).
Functional impact	None
Dependencies and prerequisites	None

Minimize external user registration link expiration duration

Manage the number of days that a registration link can be accessed.

If the *sn_ext_usr_reg.Reg_link_expiration_days* system property is not set to the recommended value of 3, then a registration link could be used by someone other than the intended user if the link is discovered later in time.

Ensure that the property *sn_ext_usr_reg.Reg_link_expiration_days* is set to 3 or less.

More information

Attribute	Description
Configuration name	*sn_ext_usr_reg.Reg_link_expiration_days*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	3
Default value	3
Fallback value	3
Category	Authentication

Attribute	Description
Security risk	• Severity score: Medium • CVSS score: 6.6 • Security risk details: Longer expiration windows weaken account provisioning security and create opportunities for unauthorized account creation or impersonation.
Dependencies and prerequisites	None

Minimize reset password max SMS per day

Manage the maximum number of SMS codes sent for verification per day by user.

The *password_reset.sms.max_per_day* system property determines the maximum number of SMS codes sent for verification per day for a user.

Set the property *password_reset.sms.max_per_day* to a value of or less.

More information

Attribute	Description
Configuration name	*password_reset.sms.max_per_day*
Configuration type	System Properties (/sys_properties_list.do)
Data type	ilteger
Recommended value	10
Default value	<none>
Fallback value	5
Category	Authentication
Security risk	• Severity score: 5.9 • CVSS score: Medium • Security risk details: If the value is too high, it's easier for attackers to brute force the SMS code.
Dependencies and prerequisites	None

Minimize failed login attempts for high assurance sessions

Decrease the likelihood of a brute force attack by minimizing failed login attempts for high assurance sessions.

Use the **glide.zta.high_assurance.session.max.login.failed_attempts** system property to limit the number of failed authentication attempts allowed before users are logged out when re-authenticating through Continuous Authentication.

Set the value of this system property to a low value (such as 5) to decrease the likelihood of a brute force attack.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Technical configuration name	glide.zta.high_assurance.session.max.login.failed_attempts
Plugin applicability	Zero Trust - Continuous Authentication (com.snc.zero_trust_continuous_authentication)
Security risk	A high number of allowed authentication attempts increases the likelihood of a brute force attack.
Common Vulnerability Scoring System (CVSS) score	3.3
Common Vulnerability Scoring System (CVSS) rating	Low
Functional impact	Users are logged out of their sessions after the number of authentication failures selected in the property.
Dependencies and prerequisites	None
Data type	Integer
Base system value	5
Fallback value	5
Recommended value	5

To learn more about adding or creating a system property, see Add a system property.

Minimize reset password request expiration duration

The *password_reset.request.expiry* denotes the time period in minutes during which a user must perform the password reset process.

If the *password_reset.request.expiry* system property is not set to the recommended value of 10 or less, then it increases the opportunity for someone else to guess and use the request and attempt to reset the password.

Ensure that the property *password_reset.request.expiry* is set to 10 or less.

Note: The setting for the *password_reset.request.expiry* property takes precedence over the setting for *glide.pwd_reset.onetime.token.validity*property that has a 12 hour default.

More information

Attribute	Description
Configuration name	*password_reset.request.expiry*

Minimize reset password SMS expiry duration

Control the number of minutes remaining before the SMS code expires.

The *password_reset.sms.expiry* system property denotes the number of minutes before the SMS code expires.

Ensure the property *password_reset.sms.expiry* is set to 5 or less.

More information

Attribute	Description
Configuration name	*password_reset.sms.expiry*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	An integer less than or equal to 5
Default value	5
Fallback value	5
Category	Authentication
Security risk	• Severity score: 5.6 • CVSS rating: Medium • Security risk details: If the value is too high, an attacker may guess the SMS code to reset the password.
Functional impact	None
Dependencies and prerequisites	None

Minimize one-time out of band verifier lifetime duration [Updated in Security Center 1.3]

Manage the time duration for out-of-band verifiers.

An out-of-band verifier is an alternative delivery method for one-time code situations. For example, resetting a multi-factor token. If this method is enabled by administrators in the Multi-factor authentication plugin, a one-time code is delivered by email. Set one-time out-of-band verifiers to expire after 10 minutes to limit the validity window. A larger time window allows more time for the code to be compromised through illicit means such as phishing, social engineering, or shoulder-surfing attacks.

More information

Attribute	Description
Configuration name	*glide.multifactor.onetime.code.validity*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer

Attribute	Description
Recommended value	10
Default value	10
Category	Authentication
Security risk	• Severity score: 3.9 • CVSS score: Low • Security risk details: Set one-time out-of-band verifiers to expire after 10 minutes. Anything longer increases the risk of the code being compromised by a bad actor.
Dependencies and prerequisites	Multi-factor authentication
References	Multi-factor Authentication criteria

Minimize SAML notBefore or notOnOrAfter constraint duration [Updated in Security Center 1.3 and 1.5]

Configure this property to add a grace period in which SAML requests and responses are considered valid.

This property adds a grace period during which SAML requests and responses are considered valid. The property value represents the number of seconds to add to the *NotBefore* and *NotOnOrAfter* constraints to account for time differences between the Identity Provider (IdP) clock, and Service Provider (SP) clock. These constraints defend against replay attacks by denying requests that aren't made within the specified time frame. If the IdP and SP clocks are significantly different, then the network latency may result in the SAML request being unauthorized.

More information

Attribute	Description
Configuration name	*glide.authenticate.sso.saml2.clockskew*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	less than 60
Default value	180
Category	Authentication
Security risk	• Severity score: 7.5 • CVSS score: High • Security risk details: Setting the property to a value of 60 or higher may prevent the constraints from defending against replay attacks.
Dependencies and prerequisites	None

Notify users during password reset/change process [Removed in Security Center 1.5]

Use this property to enable end users to reset or change passwords using a self-service process.

This property enables an end user to reset or change a password using a self-service process. Alternatively, your organization could implement a process that requires a service desk agent to reset passwords for end users. If a password change and or reset process doesn't notify users on password update, a bad actor may be able to lock that user out of their account without their knowledge. This would provide the bad actor more time to perform malicious activities. Ensure password reset process notifies users upon password change or reset.

More information

Attribute	Description
Configuration name	*pwd_process.change, pwd_process.reset*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Authentication
Security risk	• Severity score: 8.1 • CVSS score: High • Security risk details: A bad actor may be able to lock a user out of their account without their knowledge if no notification is sent to them when a password change is reset.
Dependencies and prerequisites	None

Prohibit Use of KBA as Single Factor for AI Voice

Use a system property to prevent Knowledge Based Authentication (KBA) from being the only factor of authentication required to authenticate to the platform for AI voice.

Use the *glide.voice.authenticate.allow_kba_as_only_factor* system property to prevent security questions from being the only factor of authentication required to authenticate to the platform in the AI voice agent authentication feature. Knowledge Based Authentication (KBA) allows users to answer security questions as an authentication factor. Learn more about authentication factors for AI voice agents at Explore authentication factors for AI voice agents.

Ensure that the *glide.voice.authenticate.allow_kba_as_only_factor* system property is set to `false`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.voice.authenticate.allow_kba_as_only_factor*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Authentication
Security risk	• Severity score: 3.3 • CVSS score: Low • Security risk details: Allowing users to authenticate with a single factor increases the risk of account compromise if that factor is compromised. Enforcing Multi-factor Authentication (MFA) is recommended. If single-factor access is allowed, then KBA security questions aren't recommended as the single factor. Security questions can be guessed, learned through social engineering, or obtained from public records, increasing the risk of account compromise.
Functional impact	If KBA can’t be used as a single factor of authentication, then users must use another form to authenticate to the platform for the Voice Authentication feature, such as SoftPin or SMS OTP.
Dependencies and prerequisites	AI voice agent authentication feature is setup and enabled.

Reduce allowed bypasses for multifactor setup

Decrease the window of time an account is at risk of compromise by reducing allowed bypasses for multifactor setup.

Reduce the number of times a user can skip the multifactor passcode setup requirement to decrease the window of time an account is at risk of compromise. Multifactor authentication (MFA) protects against password-related attacks or weak passwords by requiring an additional form of verification. Reducing the length of time a user can skip this setup reduces this vulnerability.

Set the **glide.authenticate.multifactor.setup.bypass.count** system property to **0** to prevent users from skipping multifactor passcode setup.

More information

Attribute	Description
Technical configuration name	glide.authenticate.multifactor.setup.bypass.count

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Plugin applicability	None.
Security risk	Multifactor authentication protects against password-related attacks or weak passwords by requiring an additional form of verification. A high number of allowed multifactor setup bypasses increases the risk of account compromise as the account isn't protected by multifactor. A small number of allowed bypasses reduces this window of time.
Common Vulnerability Scoring System (CVSS) score	3.9
Common Vulnerability Scoring System (CVSS) rating	Low
Functional impact	Users aren't allowed to login to an instance without setting up MFA if they've surpassed the number of logins specified in the property.
Dependencies and prerequisites	None
Data type	Integer
Base system value	0
Fallback value	0
Recommended value	0

To learn more about adding or creating a system property, see Add a system property.

Remove credentials from Welcome page

Modify the default content on the Welcome page to remove the default credentials.

Two **How to Login** records are installed as part of the demo data for the CMS plugin.

Note: If you do not install the demo data for an instance, these records do not exist. In that case, the configuration is considered as Security Compliant as per the recommended security practices.

More information

Attribute	Description
Name	*How to login*
Configuration type	Table: sys_home
Category	Authentication
Purpose	To remove default credentials from Welcome page that were added with demo data.
Recommended value	False or null if no demo data was utilized.
Default value	None. This is a table configuration, not a Glide property. Therefore, there is no value for default value.
Configuration type	Boolean

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	(Moderate) Demo data is provided for the CMS plugin, which includes two default passwords included on the welcome page. If this is not removed, an unauthorized attacker could gain access to the instance.

Require CAPTCHA for guest walk-up experience in customer service application

The CAPTCHA for the Guest Walk-up experience prevents unauthenticated guest users to create bookings by requiring users to complete a CAPTCHA verification.

The CAPTCHA for the Guest Walk-up experience prevents unauthenticated guest users to create bookings by requiring users to complete a CAPTCHA verification. If CAPTCHA isn't enabled, this could lead to automated creation of spam appointments to overwhelm the system or fill up all available booking spots creating a Denial of Service attack.

If Guest Walk-up Experience for Customer Service application is active, ensure that *sn_guest_walkup_cs.captcha.enabled* is set to **true**.

More information

Attribute	Description
Configuration name	*sn_guest_walkup_cs.captcha.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Authentication
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: This exposes the system to spam appointments and resource exhaustion attacks, potentially filling all available booking slots and causing a Denial of Service (DoS). Without CAPTCHA, the platform lacks a critical control to prevent automated abuse and maintain service availability.
Dependencies and prerequisites	None

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	This property enables or disables the captcha on the CSM Guest Walkup Check-in widgets. By default, it is set to true.

Require obfuscation of classic mobile app UI [Updated in Security Center 1.3]

Use the *glide.ui.m.blur_ui_when_backgrounded* property to obfuscate all fields from the snapshot as the image is saved during the backgrounding process.

On Android devices, the Android operating system takes a screenshot for usage in the recent task menu when the application is sent to background. Users can also take manual screenshots of the application, which are stored publicly on the device.

On iOS devices, the iOS operating system also allows applications to save an image file. This file represents the last screen seen by the user when the application is sent to the background. While the intent is to provide a better user experience, it also creates a security risk because the images are saved as PNG image files.

Note: This setting or configuration is per instance basis so the user must connect to the instance with the property configured.

To obfuscate all fields from the snapshot in the ServiceNow Classic app, see Configure the blur app option to improve security.

Example

When you set this property to true, the background application is obfuscated for iOS devices, and blacked out for Android iOS devices.

More information

Attribute	Description
Property/Plugin Name	*glide.ui.m.blur_ui_when_backgrounded*
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication
Purpose	To obfuscate all fields from the snapshot as the image is saved during the backgrounding process.
Recommended value	true
Security risk rating	2.4
Functional impact	If the *glide.ui.m.blur_ui_when_backgrounded* property is set to true, the native apps use the parameter defined on the server to blur the screen when the app enters the background.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• It blurs the screenshots taken by iOS and Android when the app enters the background. **Note:** Enabling this setting can prevent users from taking screenshots of the classic mobile app, which may be desirable for support purposes. • The user experience may be adversely affected because they would not be able to see the content when the app is sent to background.
Security risk	(Medium) A compromised (jailbroken) device would enable an attacker to have full access to the file system, with access those files/snapshots with sensitive information embedded in them.

To learn more about adding or creating a system property, see Add a system property.

Require obfuscation of mobile app UI

Configure the *glide.sg.blur_ui_when_backgrounded* property so that the UI of the app is blurred when the app is running in the background.

If the *glide.sg.blur_ui_when_backgrounded* system property is not set to the recommended value of **true**, then the mobile app's UI is visible when viewed from the app switcher once the app has been backgrounded.

More information

Attribute	Description
Configuration name	*glide.sg.blur_ui_when_backgrounded*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	File and resources
Security risk	• Severity score: 2.4 • CVSS score: Low • Security risk details: Blurring mobile backgrounding screenshots provides a higher level of confidentiality and privacy on the local device by blurring this view when backgrounded.
Dependencies and prerequisites	None

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description

Require Minimum and Maximum Password Length

Set minimum and maximum password lengths to avoid compliance issues and reduce the risk of a successful brute force attack

Password policies define the requirements for passwords your users create on your instance. The password length must fall within the range accepted by the NIST 800-63B document.

Allowing passwords that are too short increases the risk of an attacker successfully brute forcing passwords. Shorter passwords create significant compliance violations.

Ensure that a password policy is being enforced for each password credential store in use on your instance. Ensure that the password policy mandates a minimum password length of at least 15 characters and maximum password length of at least 64 characters.

For each password credential store record in the Password Reset Credential Stores [pwd_cred_store] table:

1. Ensure that a password policy is being enforced for each password credential store in use on your instance:

   For each password credential store record in the Password Reset Credential Stores [pwd_cred_store] table, ensure that **Enable password policy** field is activated.

2. Ensure that the password policy mandates a minimum password length of at least 15 characters and maximum password length of at least 64 characters.

   Navigate to the Password Policy [password_policy] record referenced in the record's **Password policy** field. Ensure that the **Minimum Password Length** field is set to at least 15 and **Maximum Password Length** field is set to at least 64.

3. Further instructions on configuring a password policy can be in the documentation: Enable password policies on your instance

Further instructions on configuring a password policy, see Enable password policies on your instance.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	• Boolean • Integer
Recommended value	• The **Enable password policy** field on each Password Reset Credential Stores [pwd_cred_store] record must be activated(true). • The **Minimum Password Length** on the associated Password Policy [password_policy] record must be at least 15. • The **Maximum Password Length** on the associated Password Policy [password_policy] record must be equal or less than 64.
Default value	• The **Minimum Password Length** on Password Policy [password_policy] records is 8 by default. • The **Maximum Password Length** on Password Policy [password_policy] records is 100 by default.
Fallback value	• The fallback value of **Minimum Password Length** on Password Policy [password_policy] records is 8. • The fallback value of **Maximum Password Length** on Password Policy [password_policy] record is 100.
Category	Authentication
Security risk	• Severity score: 5.9 • CVSS score: Medium • Security risk details: Allowing passwords that are too short increases the risk of an attacker successfully brute forcing passwords. Shorter passwords create significant compliance violations.
Functional impact	Instances don't suffer any impact from a minimum password length of 15 or maximum password length of at least 64.
Dependencies and prerequisites	None

Restrict basic authentication external role exemption

The *glide.authenticate.basic_auth.allow_snc_external* property controls whether users with the snc_external role are exempt from the basic authentication restriction.

The snc_external role is the base role for all external users of the instance—customers and portal constituents. Unlike the other exception checks in the Basic authentication restriction gate, this check returns unconditionally. When a user holds this role, the value of the *glide.authenticate.basic_auth.allow_snc_external* property is the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

sole, final determinant of whether that request is allowed. The property doesn't fall back to `allowed_users`, `allowed_roles`, or the `enforcement-date` tracking flow.

External and portal users have normal interactive sessions. They can complete multi-factor authentication (MFA) enrollment through the standard UI flow. Nothing in the platform blocks them from MFA enrollment the way Web Service Access Only (WSAO) accounts are blocked. Whether an external user is exempt from MFA is governed by a separate, admin-configured MFA context policy mechanism, not a technical requirement. This property doesn't compensate for a population that structurally can't satisfy MFA.

Before enforcing this restriction

1. Navigate to `/sys_properties_list.do` on the instance.
2. Identify any integration or automation accounts that hold the `snc_external` role and use Basic Auth. Migrate them to a dedicated integration role or WSAO status.
3. Set the *`glide.authenticate.basic_auth.allow_snc_external`* property to `false`.

More information

Attribute	Description
Configuration name	*`glide.authenticate.basic_auth.allow_snc_external`*
Configuration type	System Properties (`/sys_properties_list.do`)
Category	Authentication
Data type	Boolean
Recommended value	false
Default value	true
Fallback value	true
Functional impact	Setting this property to `false` requires all `snc_external` users to satisfy MFA (or use allowed_users, allowed_roles paths) to continue using Basic Auth. Before disabling, verify that external integrations or automation accounts don't depend on this role. Migrate service accounts to a dedicated integration role or WSAO status instead.
Security risk	• CVSS score: 8.1 • CVSS rating: High • The external-role check returns unconditionally. Leaving the `glide.authenticate.basic_auth.allow_snc_external` property at its default value of `true` grants every `snc_external` user an unconditional, unlogged Basic Authentication Restriction gate bypass. This applies to the entire external and customer-facing population. These users gain access regardless of MFA enrollment.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	This covers a broader population than other exception mechanisms in this control family. Unlike WSAO accounts, these users can enroll in MFA. The exemption here is a compatibility allowance, not a technical necessity. An attacker who obtains an external-role password can authenticate directly against the API. No second factor is required.
Dependencies and prerequisites	Takes effect only when *glide.authenticate.basic_auth.restriction.active* is `true`.

Restrict MID IPKI registration key retry attempts

Configure the registration key retry threshold to prevent unauthorized Management, Instrumentation, and Discovery (MID) Server registration attempts. Setting the *sn_mid_infra.registration_key.max_use_count* property limits how many times a registration key can be used before it is revoked.

The MID Internal Public Key Infrastructure (IPKI) feature uses registration keys to issue IPKI certificates to MID agents. This property controls the maximum number of failed attempts allowed before a registration key is revoked. The default value of `five` allows a limited number of retries. Lower values restrict retries further; higher values increase retry attempts.

Configure the *sc-restrict-mid-ipki-registration-key-retry* property

1. Navigate to `/sys_properties_list.do` on your ServiceNow instance.
2. Search for the *sn_mid_infra.registration_key.max_use_count* property.
3. Set the value to a number between 3-5. Don't exceed 5.

   Lower values within this range provide a more restrictive security posture while maintaining reasonable tolerance for legitimate registration failures. Save the property configuration.
4. Test the configuration by initiating a new MID IPKI registration and verify that the certificate is issued successfully.
5. Monitor MID registration logs for any revocation events indicating the retry threshold has been reached.

More information

Attribute	Description
Configuration name	*sn_mid_infra.registration_key.max_use_count*
Configuration type	System Properties (`/sys_properties_list.do`)
Data type	Integer
Recommended value	3-5
Default value	5

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Fallback value	5
Category	Authentication
Security risk	• Severity score: 5.4 • CVSS rating: Medium • Security risk details: Setting this property to a high value allows an attacker with a registration key to attempt multiple failed registrations before the key is auto-revoked. A higher retry threshold extends the attack window and can increase the opportunity to identify validation weaknesses or bypass registration controls. This can lead to unauthorized IPKI certificate issuance or compromise of MID agent identity validation.
Functional impact	Modifying this property changes the maximum number of retries allowed for a registration key on failure before permanent revocation. Setting a lower value reduces the chances of successful registration if temporary or transient failures occur during the registration process. Setting a higher value increases the likelihood of successful registration but allows more retry attempts before revocation, potentially delaying detection of persistent registration failures. Instance owners must test new MID IPKI registrations to verify that the registration key is issued successfully with the configured retry count. Beyond confirming successful registration, no additional regression testing is possible.
Dependencies and prerequisites	None

Set basic authentication restriction default decision

The *glide.authenticate.basic_auth.restriction.default_decision* property controls the automatic decision applied to basic-auth accounts during the Basic Authentication Restriction tracking period.

This property sets the decision automatically applied to a basic-auth account the first time it is detected during the Basic authentication restriction tracking period. This decision also applies to any account whose per-row entry in the Basic Auth Exception table is explicitly left as Apply default from system property.

Three outcomes are available:

- **Maintain current login**: Keeps unrestricted basic-auth access.
- **Revoke Basic Auth API login**: Blocks API basic-auth once enforcement begins. UI login is unaffected.
- **Convert to web service access only account**: Keeps basic-auth API access but blocks interactive UI login for that account, satisfying multi-factor authentication (MFA) policy because it no longer has an interactive session to protect.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.authenticate.basic_auth.restriction.default_decision*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String (Choice list)
Recommended value	Revoke Basic Auth API login-Basic Auth API login blocked; UI login allowed
Default value	Maintain current login-Basic Auth API and UI login allowed
Fallback value	Maintain current login-Basic Auth API and UI login allowed
Category	Authentication
Security risk	• Severity score: 8.1 • CVSS rating: High • Security risk details: When left at the default `Maintain current login`, two groups of accounts automatically keep unrestricted basic-auth API access. The first group: accounts first detected using basic auth during tracking. The second group: accounts an administrator leaves on `Apply default from system property`. Neither group satisfies multi-factor authentication (MFA) once enforcement begins. This creates the same credential-abuse exposure as any unrestricted basic-auth account. An attacker who obtains a valid password can use it directly against the API. They bypass the MFA that would otherwise protect interactive login. Because this is the default applied to unreviewed accounts, an instance that runs through tracking without changing this property grandfathers every detected account into permanent MFA bypass. This requires no deliberate administrator action.
Functional impact	This property only takes effect for exception-table rows resolved to **Apply default from system property**. Any per-account decision in the exception table overrides this system property default. Changing the default to `Revoke` means any account an administrator has not yet explicitly reviewed will lose basic-auth API access once enforcement begins. UI login remains unaffected. Before or immediately after changing this default, complete the review of the Basic Auth Exception table: **1.** Convert genuine integration accounts to Web Service Access (WSO) Only **2.** Explicitly grant continued access only where justified Completing this review confirms unreviewed accounts retain API access.

Attribute	Description
Dependencies and prerequisites	None

Set OTP lifetime for password reset to 1 hour [Updated in Security Center 2.0]

Control the time duration of the link in the password reset email.

The *glide.pwd_reset.onetime.token.validity* system property makes the link in the password reset email expire after the number of hours specified in the property. The validity time of a password reset token should be kept as short as possible while not disrupting normal user experience

Set the property value to 1 (in hours).

More information

Attribute	Description
Configuration name	*glide.pwd_reset.onetime.token.validity*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	1
Default value	1
Fallback value	1
Category	Authentication
Security risk	• Severity score: 4.6 • CVSS score: Medium • Security risk details: A longer validity time for password reset token gives malicious actors a wider window to perform account takeover if the email with the reset token is leaked or compromised.
Dependencies and prerequisites	None

Business Logic

This category looks at the logic and flow unique to each application with general secure principles. Specifically ensure that the intended sequence of business logic flow cannot by bypassed, that limits exist to detect and prevent automated attacks, and that protections against spoofing, tampering, information disclosure and elevation of privilege attacks exist.

The following are some security controls that an administrator can configure to restrict unauthorized access to sensitive entities within the ServiceNow AI Platform.

Limit max comments per user per day

Configure the *sn_kb_social_qa.max_comments_per_user_daily* property to restrict the number of QA comments per day.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

If the *sn_kb_social_qa.max_comments_per_user_daily* system property is not set to the recommended value of 500 or less, then there will be no restriction on number of QA comments per day.

Ensure that the property *sn_kb_social_qa.max_comments_per_user_daily* is set to 500 or less.

More information

Attribute	Description
Configuration name	*sn_kb_social_qa.max_comments_per_user_daily*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	500
Default value	500
Fallback value	500
Category	
Security risk	• Severity score: 3.7 • CVSS rating: Low • Security risk details: Too many comments could lead to resource exhaustion.
Functional impact	None
Dependencies and prerequisites	None

Limit max subscriptions per user per day

Configure the *sn_kb_social_qa.max_subscriptions_per_user_daily* property to limit the max number subscriptions a user can subscribe to in a day.

If the *sn_kb_social_qa.max_subscriptions_per_user_daily* system property is not set to the recommended value of 500 or less, then there will be no restriction on the maximum number of Social Q&A questions to which a user can subscribe to in a day.

Ensure the property *sn_kb_social_qa.max_subscriptions_per_user_daily* is set to 500 or less.

More information

Attribute	Description
Configuration name	*sn_kb_social_qa.max_subscriptions_per_user_daily*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	An integer less than or equal to 500
Default value	500

Attribute	Description
Fallback value	500
Category	Business Logic
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: Set the property value to 500 or less to prevent resource exhaustion.
Dependencies and prerequisites	None

Minimize SMTP Recipient Quantity

The *glide.email.smtp.max_recipients* specifies the maximum number of recipients the instance can list in the **To:** line for a single email notification.

The *glide.email.smtp.max_recipients* system property specifies the maximum number of recipients the instance can list in the To: line for a single email notification. Notifications that would exceed this limit instead create duplicate email notifications addressed to a subset of the recipient list. Each email notification has the same maximum number of recipients.

Ensure that the property *glide.email.smtp.max_recipients* is set to `100` or less.

More information

Attribute	Description
Configuration name	*glide.email.smtp.max_recipients*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	An integer less than or equal to 100
Default value	100
Fallback value	100
Category	Business Logic
Security risk	• Severity score: 4.9 • CVSS rating: Medium • Security risk details: This can lead to resource exhaustion and potentially cause a Denial of Service (DoS) condition on the email subsystem or the instance itself. Limiting recipient counts is essential to prevent abuse and maintain system performance and availability.
Functional impact	None
Dependencies and prerequisites	None

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

To learn more about adding or creating a system property, see Add a system property.

Timeout guest sessions

Use a system property to control the inactive session timeout for unauthenticated users.

The *glide.guest.session_timeout* property controls the inactive session timeout for unauthenticated (guest) users, specified in minutes. New instances are provisioned with a default of 5 minutes. If the property does not exist in the sys_properties table, the effective value defaults to 0. When set to 0, the guest-specific override is disabled and the session instead uses the general UI session timeout (*glide.ui.session_timeout*).

Setting the *glide.guest.session_timeout* property greater than 30 minutes increases the number of sessions persisted by the instance, which may cause minor availability concerns.

To configure this property:

- Navigate to `/sys_properties_list.do` on the instance.
- Ensure the *glide.guest.session_timeout* property exists and is set to a value greater than 0 and less than or equal to 30 minutes.

More information

Attribute	Description
Configuration name	*glide.guest.session_timeout*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer (in minutes)
Recommended value	30
Default value	5
Fallback value	0
Category	Business Logic
Security risk	• Severity score:4.3 • CVSS score: Medium • Security risk details: Setting the *glide.guest.session_timeout* property greater than 30 minutes increases the number of sessions persisted by the instance, which may cause minor availability concerns.
Functional Impact	Guest sessions that remain idle longer than the configured timeout are ended, and any session-scoped state is lost. The guest user must start a new session to continue. Small timeout values can result in an undesirable user experience as sessions expire too rapidly. If there are availability concerns from persisting too many sessions in memory, the *glide.guest.session_timeout* property can be lowered to 5.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Dependencies and prerequisites	The *glide.guest.session_timeout* property interacts with the *glide.ui.session_timeout* property. When *glide.guest.session_timeout* is set to 0, guest sessions do not receive an independent idle timeout — they fall back to using *glide.ui.session_timeout* instead.

Validate remote host

Set the property to true to prevent bad actors from using internal port scanning in your network.

If the *glide.update_set.remote.check_host* system property is not set to **true**, then the Team Development Remote Instance test feature allows an internal network port scanning through error messages.

Ensure that the property *glide.update_set.remote.check_host* is set to **true**.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.update_set.remote.check_host*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Business Logic
Security risk	• Severity score: 6.3 • CVSS score: Medium • Security risk details: An attacker may enumerate all open ports on a given host or pull response data, leading to information leak or unauthorized data access.
Functional impact	None
Dependencies and prerequisites	None

Communications

This control ensures proper encryption using strong algorithms and ciphers. This includes ensuring the recommended version of TLS is used for client connectivity, use of strong cipher suites, use of trusted and signed certificates, ensuring connections are encrypted between components and logging of connection failures.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Enforce certificate trust [Updated in Security Center 1.3, removed in 2.0, added in 7.0]

Use system properties to ensure that certificate expiration and trust are checked for certificates received from outbound HTTPS call endpoints when host verification is not performed.

When *com.glide.communications.trustmanager_trust_all* is set to **true**, then certificate expiration and trust are not checked for the certificate received from an outbound HTTPS call endpoint when host verification is not performed.

Verify that the *com.glide.communications.trustmanager_trust_all* system property is set to the recommended value of **false**. This ensures that your instance only trusts certificates that it can verify against the JVM certificate store. Self-signed and enterprise-signed certificates are not trusted. This property only applies when *com.glide.communications.httpclient.verify_hostname* is set to **false**.

Note: The values for these properties are and cannot be altered once changed (they are non-revertible). For security purposes, do not change this property value. If you have further questions, contact Customer Service and Support.

More information

Attribute	Description
Property name	*com.glide.communications.trustmanager_trust_all*
Configuration type	System Properties (/sys_properties_list.do)
Category	Communications
Purpose	To enforce certificate validation for outgoing requests.
Recommended value	false
Security risk rating	5.7
Functional impact	This remediation enforces strict validation on certificate CA (certificate authority) field. If a trusted entity (CA) issued the certificate, the instance accepts it for further use.
Security risk	(Medium) For confidentiality and integrity reasons, application should validate the certificate's CA before using the certificate for any transactional operations.
References	Certificates Verify certificate chain and hostname

Disable outbound SSLv2/SSLv3 connections

Use the *glide.outbound.sslv3.disabled* property to force the MID Server to use TLS when making outbound connections, such as REST and SOAP requests. Normally, outbound connections from an instance are forced to use TLS instead of SSL.

The *glide.outbound.sslv3.disabled* system property controls the desired transport encryption protocol. If *glide.outbound.sslv3.disabled* is not set to the recommended value of **true**, then outbound MID server connections such as REST and SOAP requests will use SSL as the transport protocol. SSL was proven to be insecure in 2014.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Ensure that the *glide.outbound.sslv3.disabled* system property exists in the System Properties [sys_properties] table and is set to the value **true**. If the property does not appear in the System Properties [sys_properties] table, add a new record.

More information

Attribute	Description
Configuration name	*glide.outbound.sslv3.disabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Communications
Security risk	• Severity score: 6.5 • CVSS rating: Medium • Security risk details: SSLv3 has been proven insecure since 2014 due to vulnerabilities like POODLE, making it susceptible to man-in-the-middle attacks and data interception. Allowing SSLv3 undermines transport encryption and exposes sensitive data in transit, violating modern security standards.
Functional impact	None
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Do not use demo certificates for active SAML configurations

Control whether demo certificates are used in production SAML configurations.

The demo certificates provided by ServiceNow should not be used in production SAML configurations. The certificates are common among all instances with known passphrase. If one of the SAML properties utilizing a certificate keystore is active (*require_signed_authnrequest*, *require_signed_logoutrequest*, or *encrypt_assertion*) then the demo data must not be used. Since demo data is shared among all instance, there is no integrity guarantee of requests signed with shared certificates.

Set up a custom keystore, following the documentation. The value of *glide.authenticate.sso.saml2.keystore* should be set to the sys_id of a custom, active keystore.

More information

Attribute	Description
Configuration name	*glide.authenticate.sso.saml2.keystore*

Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	Does not contain the sys_id `c60ad24b732220103a5b0dd43cf6a7db` or `3685fc22930212003c5537ae867ffb91`
Default value	<none>
Fallback value	<none>
Category	Communications
Security risk	• Severity score: 3.9 • CVSS rating: Low • Security risk details: Messages encrypted by the IDP could be decrypted by any actor, if intercepted.
Functional impact	None
Dependencies and prerequisites	None

Disable deprecated TLS versions

Avoid loss or leakage of sensitive data by disabling deprecated TLS versions.

Confirm that your instance only negotiates for communication via Transport Layer Security (TLS) versions 1.2 when communicating with other servers to help prevent data transfer over weaker TLS 1 and TLS 1.1 protocol versions.

Set the **com.glide.communications.disable.deprecated.tls** to **true** to use only TLS versions 1.2 and up.

More information

Attribute	Description
Technical configuration name	com.glide.communications.disable.deprecated.tls
Plugin applicability	None
Security risk	Using outdated and unsupported TLS versions could result in loss and leakage of sensitive data.
Common Vulnerability Scoring System (CVSS) score	4.4
Common Vulnerability Scoring System (CVSS) rating	Medium
Functional impact	When this property is set to **true**, older insecure servers that require a weaker TLS 1 or 1.1 protocol aren't able to communicate with your instance.
Dependencies and prerequisites	None
Data type	Boolean

Enforce OCSP check on network error

Learn how to configure the *com.glide.communications.httpclient.ocsp_allow_network_error* property to prevent bad actors from bypassing Online Certificate Status Protocol (OCSP) checks.

If this property is not set to **false**, the system treats OCSP validation as successful by default. This occurs when the Online Certificate Status Protocol (OCSP) check encounters a network-related issue such as a timeout or failure to retrieve revocation data.

1. Navigate to /sys_properties_list.do on the instance.
2. Ensure the *com.glide.communications.httpclient.ocsp_allow_network_error* property exists and is set to `false`.

More information

Attribute	Description
Configuration name	*com.glide.communications.httpclient.ocsp_allow_net*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	true
Fallback value	true
Category	Communications
Security risk	• Severity score: 5.9 • CVSS score: Medium • Security risk details: An attacker using a revoked certificate can exploit this setting by simply omitting the OCSP response during a connection attempt. In such cases, the client incorrectly accepts the revoked certificate as valid. This undermines the integrity of the Public Key Infrastructure (PKI) and the trust model that underpins secure web communications. The use of revoked certificates is often indicative of malicious activity, unless attributable to temporary synchronization issues between certificate authorities and OCSP responders.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Dependencies and prerequisites	The *com.glide.communications.httpclient.ocsp_allow_net* property has no effect unless the *com.glide.communications.httpclient.verify_revoked* property, the overall gate for certificate revocation checking, is set to `true`.
Functional impact	When the *com.glide.communications.httpclient.ocsp_allow_net* property is set to `false`, an outbound HTTPS connection is not established if the OCSP responder becomes unreachable due to a network error. Network errors include timeouts or DNS failures. Administrators should monitor OCSP responder availability after making this change, as any outbound integration with a temporarily unreachable OCSP responder will fail to connect.

Verify certificate chain and hostname

Configure the *com.glide.communications.httpclient.verify_hostname* property to prevent man-in-the-middle-attacks by ensuring that the certification verification process is executed.

When the *com.glide.communications.httpclient.verify_hostname* property is not set to the secure value of **true**, the hostname and certificate chain presented by remote hosts during a TLS connection initiated from the ServiceNow instance are not validated.

This vulnerability compromises the security of the TLS connection and allows person-in-the-middle attacks, where communications between two parties are intercepted. This may lead to sensitive data disclosure.

Ensure that the *com.glide.communications.httpclient.verify_hostname* system property is set to the secure value of **true**.

More information

Attribute	Description
Configuration name	*com.glide.communications.httpclient.verify_hostnam*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Communications
Security risk	• Severity score: High • CVSS score: 7.4 • Security risk details: This vulnerability compromises the security of the TLS connection and allows person-

Attribute	Description
	in-the-middle attacks, where communications between two parties are intercepted. This may lead to sensitive data disclosure.
Dependencies and prerequisites	The *com.glide.communications.httpclient.verify_hostnam* property governs hostname and certificate chain validation independently of the *com.glide.communications.httpclient.verify_revoked* property, the overall gate for certificate revocation checking.
Functional impact	When the *com.glide.communications.httpclient.verify_hostnam* property is set to **true**, an outbound HTTPS connection is rejected if the remote host's certificate does not match the requested hostname or its certificate chain can't be validated. Outbound integrations to hosts with a mismatched or misconfigured certificate will fail to connect once this property is set to true.

Verify certificate revocation

The *com.glide.communications.httpclient.verify_revoked_certificate* property checks certificate revocation during the Transport Layer Security (TLS) handshake to ensure that security checks aren't bypassed.

If the *com.glide.communications.httpclient.verify_revoked_certificate* property isn't configured to the recommended value of **true**, certificate revocation checks will be skipped during the TLS handshake.

This creates a critical security gap, potentially allowing an attacker to use a revoked certificate undetected and compromise the integrity of the Public Key Infrastructure (PKI) and the trust model that underpins secure web communications.

1. Navigate to /sys_properties_list.do on the instance.
2. Ensure the *com.glide.communications.httpclient.verify_revoked_certificate* property doesn't exist in the sys_properties table or is set to **true**.

More information

Attribute	Description
Configuration name	*com.glide.communications.httpclient.verify_revoked*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Default value	true
Recommended value	true
Default value	true
Category	Communications

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 6.5 • CVSS score: Medium • Security risk details: Not setting the *com.glide.communications.httpclient.verify_revok* property to the recommended value of **true**, creates a critical security gap, potentially allowing an attacker to use a revoked certificate undetected and compromise the integrity of the Public Key Infrastructure (PKI) and the trust model that underpins secure web communications.
Dependencies and prerequisites	None
Functional impact	When the *com.glide.communications.httpclient.verify_revoked* is set to **true**, every outbound HTTP request over TLS has its certificate checked for revocation using OCSP or CRL, as governed by the other properties in this family. When this property is set to **false**, no revocation checking is performed at all for outbound TLS connections, regardless of how the other certificate-revocation properties are configured.

Configuration

The Configuration category ensures applications have a secure build environment and hardened third party library components. Specifically, ensuring a build and deploy pipeline is repeatable and includes automated testing and prevents known security issues from being deployed. This includes keeping dependencies up to date and free from known vulnerabilities.

Allow CORS origins for OAuth endpoints

Use a system property to configure to specify which domains are allowed to make cross-origin requests.

ServiceNow can function as an OAuth authorization server, a resource server, or both simultaneously. When browser-based applications must access ServiceNow's OAuth endpoints, such as the authorization server metadata, protected resource metadata, or token endpoint, the browser's same-origin policy blocks these cross-origin requests by default. Configure the Access-Control-Allow-Origin header for these endpoints to specify which domains are allowed to make cross-origin requests.

References:

- OAuth Authorization Server Metadata RFC
- OAuth Protected Resource Metadata RFC

When integrating third-party solutions with ServiceNow OAuth functionality, ensure that the *glide.oauth.cors.allowed.origin* system property exists in the system properties [sys_properties] table, and holds the external domain(s) required for Cross Origin Resource Sharing (CORS) functionality.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.oauth.cors.allowed.origin*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	Varies based on use case. This property can one of these values: **1.** An empty string **2.** A single hostname **3.** An asterisk (*), which allows all origins to access the OAuth endpoints. **Tip:** There's no dynamic list for allow-listing multiple hostnames. Use an asterisk(*) to access the OAuth endpoints from multiple domains.
Default value	empty string
Fallback value	empty string
Category	Configuration
Security risk	• Severity score: 3.5 • CVSS score: Low • Security risk details: A third party applications inability to interact with the ServiceNow platform due to browsers' single origin policy may cause a denial of service.
Functional impact	This property can be used to connect MCP clients to the instance when the client exists entirely in the browser, and does not make token or discovery calls via a backend call to the ServiceNow platform.
Dependencies and prerequisites	None

Auto set content type options [Removed in Security Center 1.3.3]

Configure the Auto set content type options property on your instance to prevent MIME confusion attacks.

Use this property to control the X-Content-Type-Options response HTTP header. The X-Content-Type-Options response HTTP header is used by the server to indicate that the MIME types advertised in the Content-Type headers should be followed. If this property is set to false, then it is possible for an attacker to conduct MIME confusion attacks; if set to true then this header will prevent the browser from interpreting files as anything but the content type in the HTTP headers.

Warning: The value for this property is a no DB override. It can't be altered or overridden.

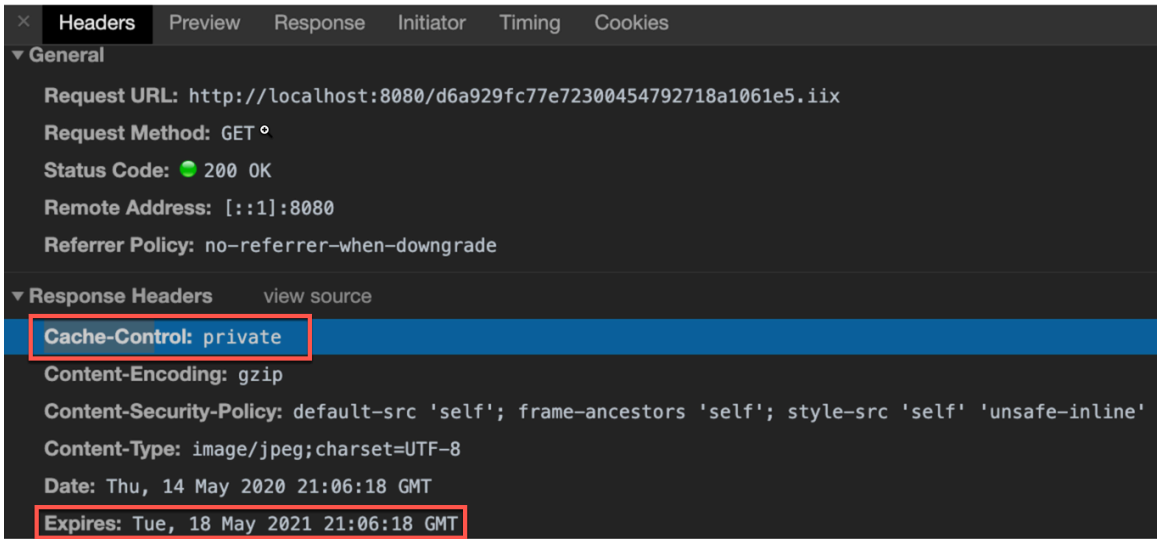
More information

Attribute	Description
Configuration name	*glide.security.header.auto_set_x_content_type_opti*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Configuration
Security risk	• Severity score: 7.3 • CVSS score: High • Security risk details: Setting this property to **false** could make it possible for an attacker to conduct MIME confusion attacks.
Dependencies and prerequisites	None
References	Add a system property

Cache-Control HTTP Header Value [Updated in Security Center 1.3 and removed in 1.5]



Use the *glide.http.cache_control* property to set the default cache-control value in the HTTP response headers that the ServiceNow AI Platform sends when requesting static content data for a page. Examples of static content include images, CSS, and JavaScript rendered from within, for a page.

The *glide.http.cache_control* property sets the default Cache-Control value in HTTP response headers to **private** or **public**. The default is **private**.

Value	Description
private	Static content can be cached at the browser (client) level, but not at the proxy server level.
public	Static content can be cached at the browser (client) level, and also at the proxy server level.

The Expires value in the HTTP response headers control when the static content expires, and has a default value of 369 days. To manually override the default value, use the *glide.http.expire.days* property.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note: You can use the *glide.http.cache* property designate whether to enable or disable setting of the Cache-Control and Expires values in HTTP response headers. Its default is **true**, which allows you to set the:

- Cache-Control value default using the *glide.http.cache_control* property.
- Expires value default using the *glide.http.expire.days* property.

More information

Attribute	Description
Property name	*glide.http.cache_control*
Configuration type	System Properties (/sys_properties_list.do)
Category	Configuration
Purpose	To configure the Cache-Control HTTP response header value for static content.
Recommended value	private
Default value	private
Security risk rating	4.3
Functional impact	Sets the default Cache-Control value in an HTTP response header.
Security risk	(High) If you set this property to **public**, instances with CDN/proxies may cache static content and render without authentication. • **private** is a more appropriate setting for instances with CDN/proxy setup. • If an the instance does not have a CDN/proxy setup, either value should be fine.

To learn more about adding or creating a system property, see Add a system property.

Enable HTTP response headers configuration

Reduce the risk of cookie/session-related hijacking of web apps using a system property.

If the *glide.http.headers_config.enabled* system property isn't set to **true**, then response header configurations defined in the HTTP Response Headers [sys_response_header] table aren't used. Security related HTTP response headers include Content Security Policy, which aids in XSS-related protections. For details on HTTP response headers, see http-response-header.

Ensure that the property *glide.http.headers_config.enabled* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.http.headers_config.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Session management
Security risk	• Severity score: 5.5 • CVSS score: Medium • Security Risk: The security risks of missing, incorrect, or weak HTTP response headers may allow for XSS, CSRF, and cookie/session related hijacking of web apps.
Dependencies and prerequisites	None

Disable legacy JQuery UI usage

Avoid the introduction of unpatched vulnerabilities in the library by disabling legacy JQuery UI usage.

Prevent the use of older prepatched JQuery UI versions, which introduce unpatched vulnerabilities in the library. Using old versions can potentially lead to security risks arising from attacks on vulnerabilities discovered in outdated JQuery UI library versions.

Confirm that the **glide.jquery_ui.legacy** system property is set to **false** to prevent older prepatched JQuery UI versions from being used. This system property is a failsafe in case organizations depend on the non-patched versions to run their custom implementations.

To learn more about adding or creating a system property, see Add a system property.

Enforce secure referrer policy

Use the *com.glide.security.referrerpolicy* property to ensure that the Referrer-Policy HTTP header sends the appropriate level of data to each ServiceNow® page to help prevent data leaks.

Use the *com.glide.security.referrerpolicy* system property to control what information is included in the referrer HTTP header across the Now Platform. The data included in the referrer header, according to the policy of this property, is the origin, path, and query strings of the full referrer URL. These values are the standardized Referrer-Policy values supported by the HTTP protocol with the addition of the value "default." Depending on the policy set by this property, the referrer header may include sensitive information about or from the entity making the request.

Ensure that the *com.glide.security.referrerpolicy* system property is set to one of the following: `default`, `same-origin`, `origin-when-cross-origin`, or `strict-origin-when-cross-origin`.

More information

Attribute	Description
Configuration name	*com.glide.security.referrerpolicy*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	default
Default value	default
Fallback value	default
Category	Configuration
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: When the *com.glide.security.referrerpolicy* system property is set to `no-referrer-when-downgrade` or `unsafe-url`, the referrer header of a request to a site different to the origin includes the full URL for the referring page making the request. The full referrer URL shared with external sites may include sensitive information from or about your instance. This can lead to data leakage and privacy violations. When the property is set to `no-referrer`, `origin`, or `strict-origin`, the referrer header is either

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	not included, or includes only the origin portion of the referrer URL when requests are sent to the origin. This change may impede efforts to trace attack paths in the logs when a security incident occurs, as the exact origin of a request can't be determined easily. Proper configuration of this property is essential to help prevent unauthorized disclosure of internal identifiers or confidential parameters while allowing for security incident investigations.
Functional impact	When the *`com.glide.security.referrerpolicy`* system property is set to `no-referrer`, `origin`, or `strict-origin`, the referrer header is either not be included, or includes only the origin portion of the referrer URL when requests are sent to the origin. This change can break functionality that requires this data. Some sites like YouTube require embedded link requests to include at least the origin in the referrer header (for example, the "origin-when-cross-origin" policy). The appropriate value of this property is dependent on the instance owner and use case. Those we recommend are described here. These policies are secure and don't break base system functionality. More information of these and the other standardized policies can be found at https://developer.mozilla.org/en-US/docs/Web/HTTP/Reference/Headers/Referrer-Policy. • `default`: Functionally equal to setting the value to `same-origin` • `same-origin`: Sends the origin, path, and query string for same-origin requests. Doesn't send the referrer header for cross-origin requests. • `origin-when-cross-origin`: When performing a same-origin request, sends the origin, path, and query string. Sends only the origin for cross-origin requests and requests to less secure destinations (from HTTPS to HTTP). • `strict-origin-when-cross-origin`: Sends the origin, path, and query string when performing a same-origin request. For cross-origin requests, sends the origin only when the protocol security level stays same (from HTTPS to HTTPS). Doesn't send the referrer header to less secure destinations (from HTTPS to HTTP).
Dependencies and prerequisites	None
References	Referrer-Policy

Ensure minimum private key size

Use a system property to determine the minimum size of the private key used for Certificate Signing Request (CSR) generation with the Certificate Inventory Management application.

The *sn_disco_certmgmt.private_key_size* system property determines the minimum size of the private key used for CSR generation with the Certificate Inventory Management application. Valid choices are 512, 1024, 2048, or 4096.

Verify that this property is set to a value of 2048 or higher. Valid choices for this property are 512, 1024, 2048, or 4096. If the property doesn't exist in the System Properties [sys_properties] table, or the value is invalid, the value is 2048 by default.

More information

Attribute	Description
Configuration name	*sn_disco_certmgmt.private_key_size*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer, representing the size of the private key generated. Use values of 512, 1024, 2048, or 4096.
Recommended value	2048
Default value	2048
Fallback value	2048
Category	Communications
Security risk	• Severity score: 3.1 • CVSS score: Low • Security Risk: Using keys smaller than 2048 can result in future information disclosure in the event the key is brute forced. Use a valid value greater than or equal to 2048 to future proof the key for a longer time period.
Functional impact	Legacy systems and applications may not handle keys greater than or equal to 2048.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Implement the x-frame-options: SAMEORIGIN security header

Use the *glide.set_x_frame_options* property to set the X-Frame-Options response header to SAMEORIGIN for all UI pages.

The *glide.set_x_frame_options* system property controls the implementation of the security header X-Frame-Options: SAMEORIGIN. If *glide.set_x_frame_options* is not set to the recommended value of **true**, then an instance will be allowed to be framed in an iframe of another page.

Ensure the property *glide.set_x_frame_options* is set to **true**.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.set_x_frame_options*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Configuration
Security risk	• Severity score: 5.9 • CVSS rating: Medium • Security risk details: This can lead to a clickjacking attack.
Functional impact	This remediation enforces the restriction for rendering a ServiceNow AI Platform application in a third-party application in the form of an iFrame. If you have such an integration, the application wouldn't render in the customized third-party app.
Dependencies and prerequisites	None

Require write access to access service catalog add item page

Use the *glide.sc.request.add_item_write_access* property to prevent unauthorized operations from being performed on catalog items.

When the *glide.sc.request.add_item_write_access* system property is not set to **true**, any logged in user can access the *Add Catalog Item* UI page. This could result in unauthorized operations performed on catalog items.

Set *glide.sc.request.add_item_write_access* property to **true**.

More information

Attribute	Description
Configuration name	*glide.sc.request.add_item_write_access*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Configuration

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: This creates a risk of unauthorized modifications or additions to catalog items, potentially leading to service disruption, fraudulent requests, or exposure of sensitive data. Misconfigured access controls in catalog management can undermine system integrity.
Dependencies and prerequisites	None
Functional impact	When the property is true, the user must have write access to the record in the context of the UI page.

Set Xframe options to prevent embedding third-party websites

Configure this property to prevent the content of a web-application from being embedded in a third-party site.

If the *com.glide.cs.embed.xframe_options* system property is not set to the recommended value of DENY or SAMEORIGIN, then content of the web application could be embedded in a third-party site using an ALLOW-FROM URI.

Ensure the property *com.glide.cs.embed.xframe_options* is set to DENY or SAMEORIGIN.

More information

Attribute	Description
Configuration name	*com.glide.cs.embed.xframe_options*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	DENY or SAMEORIGIN
Default value	sameorigin
Fallback value	<empty>
Category	Configuration
Security risk	• Severity score: 3.1 • CVSS score: Low • Security risk details: Allowing untrusted third-party sites could enable attacks such as clickjacking.
Dependencies and prerequisites	None

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data protection

The data protection category addresses the elements of confidentiality, integrity and availability (CIA) of data.

The CIA components are:

- Confidentiality: Data is protected from unauthorized access in transit and at rest.
- Integrity: Data is protected from unauthorized creation, deletion or change.
- Availability: Data is accessible when required.

Remove remember me

Use the *glide.ui.forgetme* property to remove the **Remember Me** check box from the login page to prevent login information from being cached.

The *glide.ui.forgetme* system property controls the **Remember Me** check box from the login page to prevent login information from being cached when set to **true**. If the value is set to **false**, caching of authentication information is allowed and the **Remember Me** checkbox is displayed.

Ensure that the property *glide.ui.forgetme* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.ui.forgetme*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Data protection
Security risk	• Severity score: 3.5 • CVSS rating: Low • Security risk details: This increases the risk of unauthorized access if the device is shared, lost, or compromised, as cached credentials can allow attackers to bypass authentication.
Functional impact	None
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property

Clear pasteboard when app backgrounds

The *glide.sg.clear_pasteboard_when_backgrounded* property controls if text copied from ServiceNow mobile app is kept in the clipboard and pasteboard after the app is in

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

background mode. If it is not set to the recommended value of `true`, then sensitive information may be disclosed to the Android or iOS clipboard where it can be exposed to other applications on the device.

The *glide.sg.clear_pasteboard_when_backgrounded* system property controls if text copied from ServiceNow mobile app is kept in the clipboard and pasteboard after the app is in background mode.

Ensure that *glide.sg.clear_pasteboard_when_backgrounded* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.sg.clear_pasteboard_when_backgrounded*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	true
Category	Data protection
Security risk	• Severity score: 3.5 • CVSS rating: Low • Security risk details: This creates a risk of sensitive information disclosure, as clipboard data can be accessed by other applications on the device, potentially exposing credentials, PII, or confidential business data. Enforcing this property helps prevent unintended data leakage across apps.
Functional impact	None
Dependencies and prerequisites	None

Restrict HR case updates from personal emails

Use the *sn_hr_core.restrict_guest_email* property to control whether a user can respond back to a HR case with their personal email.

When the *sn_hr_core.restrict_guest_email* system property is not set to **true**, a user can send an email from a personal account referencing the HR case to be included in the worknotes. This could result in minor confidentiality or integrity issues if the personal email is compromised or communicating insecurely. An admin may want to restrict the ability of users to respond to HR cases via their personal email, since they can't be confident of the user accessing the personal email account.

Set the property *sn_hr_core.restrict_guest_email* to '**true**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*sn_hr_core.restrict_guest_email*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Data protection
Security risk	• Severity score: 3.5 • CVSS score: Low • This creates a risk of minor confidentiality and integrity issues because personal email accounts may be insecure or compromised, and administrators cannot verify the identity or security posture of those accounts. Allowing this behavior weakens control over sensitive HR communications and increases exposure to data leakage.
Dependencies and prerequisites	None
Functional impact	This property controls whether or not a reply from a personal email address will update an HR Case. Set to true, any reply from personal email will be added to the case notes. If false, the case and notes will not be updated.

Restrict oauth parameters to POST body

Use the *glide.oauth.allow.parameters.in.post.body.only* property restricts OAuth credentials to POST request bodies when set to `true`.

Use the *glide.oauth.allow.parameters.in.post.body.only* property to control how the OAuth token endpoint (*/oauth_token.do*) accepts OAuth credentials. When set to `true`, this property restricts OAuth parameters (such as client_id, client_secret, authorization codes, and refresh tokens) to POST request bodies only. OAuth credentials submitted using HTTP headers continue to be accepted.

To set up this property:

1. Navigate to `/sys_properties_list.do` on the ServiceNow instance.
2. Ensure *glide.oauth.allow.parameters.in.post.body.only* exists and is set to `true`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.oauth.allow.parameters.in.post.body.only*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Fallback value	false
Default value	true
Category	Data protection
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: If *glide.oauth.allow.parameters.in.post.body.only* isn't set to the recommended value of **true**, OAuth credentials such as client_id, client_secret, authorization codes, and refresh tokens could be present in the URL query string. These credentials could linger in client and infrastructure logs and potentially lead to account takeover if those logs are leaked.
Dependencies and prerequisites	Plugin OAuth 2.0
References	• OAuth 2.0 • Manage OAuth tokens
Functional impact	Ensures that oauth_token.do processor accepts only POST body parameters as input for all supported grant types.

Error handling and logging

The error handling and logging category addresses the quality and verbosity of logged information exposed to stakeholders.

This includes ensuring logs and error messages do not collect sensitive information, correctly protect data according to classification and have an appropriate lifetime. Additionally, this category relates to appropriate error handling and not revealing sensitive errors to end users, such as verbose stack traces for unhandled exceptions with security implications.

Disable logger for low privilege users in script sandbox

Manage Glide System's ability to log scripts being executed in the sandbox environment.

If the *glide.security.sandbox_no_logging* system property is set to **false**, then logging is available for low-privileged users using sandboxed scripts. This property controls your instance's ability to log scripts being executed in the sandbox environment.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Ensure that the *glide.security.sandbox_no_logging* property is set to **true** to prevent low-privileged users using a sandboxed script to have logging functionality.

More information

Attribute	Description
Configuration name	*glide.security.sandbox_no_logging*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Error handling and logging
Security risk	• Severity score: 2.2 • CVSS score: Low • Security risk details: A low-privileged user could inject logs allowing the malicious user to potentially obfuscate an attack.
Dependencies and prerequisites	None

Disable secure cookie debugging

Manage the log messages related to cookies in your instance.

If the *glide.secure_cookie.debug* system property isn't set to the default value of **false**, then debug messages in the SecureUserCookie and Cookie class are logged in localhost log.

Ensure that the property *glide.secure_cookie.debug* is set to **false**.

More information

Attribute	Description
Configuration name	*glide.secure_cookie.debug*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Error handling and logging

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: Logging debug messages from the SecureUserCookie and Cookie class could lead to sensitive information disclosure.
Dependencies and prerequisites	None

Disable SQL error messages

Use the *glide.db.loguser* property to disable SQL error messages from rendering in a browser.

If *glide.db.loguser* is not set to the recommended value of **false**, then sensitive server-side error messages could be displayed to end-users. Error messages can include stack traces and information about the structure of the database that could provide an attacker the knowledge needed to perform successful SQL Injection should the preconditions exist.

Ensure that the *glide.db.loguser* system property is set to **false**.

More information

Attribute	Description
Property name	*glide.db.loguser*
Configuration type	System Properties (/sys_properties_list.do)
Category	Error handling and logging
Purpose	To disable SQL error messages from displaying within the browser.
Type	Boolean
Recommended value	false
Default value	false
Fallback value	true
Security risk rating	3.1
Functional impact	This remediation disables rendering of SQL error messages. There is no impact to any functionality.
Security risk	(Medium) No sensitive SQL information that could help an attacker should appear as a part of error message on a web page.

More information

Attribute	Description
Configuration name	*glide.db.loguser*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	<none>
Fallback value	true
Category	Error handling and logging
Security risk	• Severity score: 3.1 • CVSS rating: Low • Security risk details: Messages can include stack traces and database structure details, which attackers can leverage to craft targeted SQL injection attacks if other vulnerabilities exist. Exposing internal error information increases the risk of exploitation.
Functional impact	None
Dependencies and prerequisites	None

Enable Identity and Access Audit tool

Use Identity and Access Audit to track changes to user accounts, groups, and roles.

Use Identity and Access Audit to track critical information about modifications made to user accounts, groups, and roles. Enable this feature to help detect malicious users, track unusual activity on your instance, and adhere to compliance standards for tracking access changes.

This tool stores audit records of successful create, update, and delete transactions to the Security Table Audits [sys_security_table_level_audit] table.

Important: Identity and Access Audit doesn't audit successful read transactions, or any unsuccessful transactions.

Ensure that the Identity Security Audit (*com.glide.security.audit*) plugin is installed. After the plugin is installed, ensure that the *glide.identity.security.audit.enabled* system property is set to `true`, or doesn't exist in the System Properties [sys_properties] table.

More information

Attribute	Description
Configuration name	• *glide.identity.security.audit.enabled* • *com.glide.security.audit*
Configuration type	• Plugin (**All** > **System Definition** > **Plugins**) • System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	• N/A • Boolean
Recommended value	• Plugin is active • true
Default value	• Plugin is active • true
Fallback value	• N/A • true
Category	Error handling and logging
Security risk	• Severity score: 4.6 • CVSS score: Medium • Security risk details: Not auditing changes to user accounts, groups, and roles limits the effectiveness of audit and security personnel during investigations.
Functional impact	None
Dependencies and prerequisites	None

Enable MID audit log

The MID Server command audit log records details such as the command name, command hash, name of credential used, and execution status.

The MID Server command audit log tracks details such as the command name, command hash, name of credential used and execution status. When enabled, users with the *agent_security_admin* role can view these logs in the MID Server Command Audit Logs [ecc_agent_command_audit_log] table. Navigate to **All** > **MID Server** > **Audit Logs** > **Command Audit Logs** to see this table.

Set *mid.log.command_audit.enable* property to **true** in the MID Server Properties [ecc_agent_property] table for each MID Server to turn on auditing for commands run by the MID Server.

For more details on setting this property, see MID Server command audit log.

For information about MID Servers and how they work, see MID Server.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*mid.log.command_audit.enable*
Configuration type	MID Server Property [ecc_agent_property] record
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	false
Category	Error handling and logging
Security risk	• Severity score: 4.4 • CVSS score: Medium • Security risk details: In the event of security investigation, this table can be used by incident response teams to audit the commands run on the MID Server. Without this log, there might not be sufficient details to respond to situations such as unauthorized account use.
Functional Impact	None
Dependencies and prerequisites	This setting only applies to instances using an active Management, Instrumentation, and Discovery (MID) Server. A MID Server enables communication and movement of data between a ServiceNow instance and external applications, data sources, and services. Setting up a MID Server requires downloading the MID Server package on a Linux or Windows host, setting up the connection with the given ServiceNow instance and configuring additional settings. Information and references can be found at MID Server. After it has been set up, a MID Server appears as a record in the MID Servers [ecc_agent] table on connecting instance.

Enable protected tables plugin

Use the *com.glide.security.protected_table.enabled* property to prevent higher privilege users from tampering with log tables.

When the *com.glide.security.protected_table.enabled* system property is set to **true**, The Protected Tables plugin is utilized to prevent higher privilege users on an instance from tampering with log tables. The following logging tables will have special protections when this property is set to **true**:

- syslog (config not modifiable)
- syslog_transaction
- sys_outbound_http_log

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- sysevent
- sys_audit
- sys_push_notification
- protected_table_configuration (config not modifiable)
- syslog_app_scope

To enable table protection through the guided activation flow:

- Navigate to the Protected Tables plugin's guided activation flow.
- Complete the activation process to enable table protection. Only users with the security_admin role can activate this control.

Important: Don't turn on this control by directly editing the *com.glide.security.protected_table.enabled* property outside that guided activation flow. Default protected tables: syslog, syslog_transaction, sys_outbound_http_log, sysevent, sys_audit, sys_push_notification, protected_table_configuration, syslog_app_scope.

To extend protection to additional tables, configure insert, update, and delete protection rules for each additional table and operation in the protected_table_configuration list.

More information

Attribute	Description
Configuration name	*com.glide.security.protected_table.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	false
Category	Error handling and logging
Security risk	• Severity score: 4.0 • CVSS rating: Medium • Security risk details: When turned off (the default), Protected Tables protections don't apply, allowing maintenance-role users to modify or delete critical audit and security logs without detection. An attacker with maintenance credentials could tamper with syslog, sys_audit, and sysevent entries to cover malicious activity and evade forensic investigation. Disabling this property compromises the audit trail needed to detect and investigate security incidents.
Functional impact	Enabling the *com.glide.security.protected_table.enabled* property causes create, update, and delete attempts

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	on tables in the Protected Table Configuration list to be evaluated. Depending on that table's configured protection level, the attempt is blocked, logged, or ignored. The level shipped per table is not fixed. It depends on how long the Protected Tables plugin has been installed, so confirm the actual values on your instance rather than assuming a table is blocking. One exception holds everywhere: insert attempts on sysevent are never blocked or logged, since normal processing inserts sysevent records continuously. A refused attempt shows the message `Modifications to '<table>' have been refused due to the Protected Table configuration. Please contact your system administrator.` Any integration or business rule currently writing to or deleting from a blocking table will start failing once this property is enabled.
Dependencies and prerequisites	None

Log all outbound http request fields [Removed in Security Center v1.3.2]

Configure the *glide.outbound_http.security.log.allow.all.fields* property to false to prevent sensitive Outbound HTTP fields from being logged in plain text.

If this property is not set to the recommended value of **false**, sensitive Outbound HTTP fields might be logged in plaintext. This can decrease the security posture of your enterprise network because outbound requests with sensitive data and credentials can be logged in plaintext which is unencrypted, and can be viewed by lower-privileged users.

More information

Attribute	Description
Configuration name	*glide.outbound_http.security.log.allow.all.fields*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Category	Error handling and logging
Security risk	• Severity score: 6.8 • CVSS score: Medium • Security risk details: Not setting this property to **false** increases the chance of sensitive outbound fields being logged in plaintext which is a security risk.
Dependencies and prerequisites	None

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Log html sanitization [Removed in Security Center 2.0]

Configure *glide.html_sanitize.discarded_log.enable* property to determine if HTML sanitization events will be logged in your instance.

If this property is not set to the recommended value of **true**, HTML sanitization events are not logged in the *sys_log* table. Lack of logging could negatively impact your instance automated security detection and investigation capabilities.

More information

Attribute	Description
Configuration name	*glide.html_sanitize.discarded_log.enable*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Error handling and logging
Security risk	• Severity score: 2.4 • CVSS score: Low • Security risk details: If this property is not set to the recommended value of **true**, HTML sanitization events are not logged in the *sys_log* table which could impact automated security detection and investigation capabilities.
Dependencies and prerequisites	None
References	Enabling HTML sanitizer

Log Impersonation History

Enable impersonation history logging using a system property.

The impersonation history log tracks the following impersonation details on the Impersonation History [sys_user_impersonation_history] table when an impersonation is performed using the UI.

- Impersonating user
- Impersonated user
- Impersonation start and end times
- SessionID

Ensure that the *identity.impersonation.history.enabled* property doesn't exist in the System Properties [sys_properties] table, or exists and is set to a value of `true`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*identity.impersonation.history.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Error handling and logging
Security risk	• Severity score: 4.9 • CVSS score: Medium • Security risk details: When this property is set to `true`, impersonation session details are logged in the Impersonation History [sys_user_impersonation_history] table. Use this information for auditing in security investigations or for compliance purposes.
Functional Impact	When this property is set to `true`, impersonation session details are logged in the Impersonation History [sys_user_impersonation_history] table. When set to `false`, the impersonation details aren't captured this table.
Dependencies and prerequisites	None

Log session audit events

Use a system property to enable creations of session audit events

When the *glide.authenticate.session_access.log_audit_event* system property is set to **true**, session audit events are created in the sys_session_access_audit table. Information logged will include user, session ID (non-sensitive), IP address, roles, and policies.

Ensure the that the property *glide.authenticate.session_access.log_audit_event* is set to **true**.

Important: The *glide.authenticate.session_access.log_audit_event* system property is specific to Zero trust access. For more information, see Zero Trust Access (ZTA).

More information

Attribute	Description
Configuration name	*glide.authenticate.session_access.log_audit_event*
Configuration type	System Properties (/sys_properties_list.do)

Attribute	Description
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Error handling and logging
Security risk	• Severity score: 6.3 • CVSS score: Medium • Security risk details: Information about who accessed a session will not be logged to assist in incident investigations.
Dependencies and prerequisites	None

Log user impersonation

Configure *glide.sys.log_impersonation* to control if user-impersonating events are logged in your instance.

If *glide.sys.log_impersonation* is not set to the recommended value of **true**, then user-impersonating events are no longer logged.

Ensure that the property *glide.sys.log_impersonation* exists in the System Properties [sys_properties] table and is set to **true**. If the property does not appear in the System Properties [sys_properties] table, add a new record.

More information

Attribute	Description
Configuration name	*glide.sys.log_impersonation*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Error handling and logging
Security risk	• Severity score: 6.4 • CVSS score: Medium • Security risk details: ServiceNow's automated security detections and security investigation capabilities effectiveness is reduced.
Dependencies and prerequisites	None

Attribute	Description
References	Impersonating users

Prevent verbose HTTP request logging

Help prevent access to sensitive information by reducing verbose HTTP request logging.

The two properties *glide.outbound_http_log.override* and *glide.outbound_http_log.override.level* work together to control the level of logging for outbound HTTP requests. When *glide.outbound_http_log.override* is set to **true**, the log level for requests and responses is controlled by *glide.outbound_http_log.override.level*. If the override level is set to **all** or **elevated**, then request and response headers are logged.

Ensure that *glide.outbound_http_log.override* is not set to **true** and that *glide.outbound_http_log.override.level* is not set to **all** or **elevated**. If these properties do not appear in the System Properties [sys_properties table], they are in a secure state.

More information

Attribute	Description
Configuration name	• *glide.outbound_http_log.override* • *glide.outbound_http_log.override.level*
Configuration type	System Properties (/sys_properties_list.do)
Data type	• Boolean • String
Recommended value	• false • basic
Default value	• false • <blank>
Fallback value	• false • <blank>
Category	Error handling and logging
Security risk	• Severity score: 5.0 • CVSS rating: Medium • Security risk details: The headers logged through verbose settings for these properties can include sensitive information such as Authorization headers or cookies which can be used like credentials to

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	access the requested resource. Any user who has access to the Outbound HTTP Logs table (sys_outbound_http_log) can view this information changing their scope of access. The severity would depend on what type of outbound requests are made.
Functional impact	The **glide.outbound_http_log.override** system property enables you to override outbound http request log level. A value of **false** defaults the log level to basic. If **glide.outbound_http_log.override** is set to **true**, the level of logging is determined by the value of the **glide.outbound_http_log.override.level** property. This value can be **basic**, **elevated**, or **all**. All 3 are string/text based values. Any value other than these is interpreted as **basic**. For additional details, see Configure outbound logging.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Restrict exposure of validation error details to end users

Configure the platform to return generic error messages instead of detailed validation error text to end users in conversational AI interfaces when skill validation fails.

The *glide.cs.enable_validation_error_messages* property controls whether the platform returns detailed validation and actionable error messages to end users in a conversational AI interface when skill validation fails during a conversation. At the recommended setting of `false`, the platform withholds the specific validation-failure text extracted from internal skill-validation errors and returns only a generic context-profile message. This limits the amount of internal system detail exposed through the conversational interface.

To configure this property:

1. Navigate to `/sys_properties_list.do` on the ServiceNow instance.
2. Verify the *glide.cs.enable_validation_error_messages* property is set to `false`.

More information

Attribute	Description
Configuration name	*glide.cs.enable_validation_error_messages*
Configuration type	System Properties (`/sys_properties_list.do`)
Data type	Boolean
Recommended value	false

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Default value	false
Fallback value	false
Category	Error handling and logging
Security risk	• Security risk rating: Medium • CVSS score: 4.3 • Security risk details: Displaying detailed internal error text to end users can reveal implementation details about how a system validates and processes requests. An attacker who receives this information can use it to understand internal logic, identify weaknesses, and craft more effective targeted attacks. Sensitive operational details may also be disclosed to users who have no legitimate requirement to see them. Failure to enforce this control may result in information disclosure that helps an attacker map the system and escalate an intrusion.
Functional impact	Changing this property affects only the error message returned to end users from conversational AI skills. No other flows or features read this property. Availability risk is low because the change only toggles which error string is returned, not control flow. Regression-test the affected conversation flow and confirm end users see the generic message rather than the detailed validation error text after deployment.
Dependencies and Prerequisites	None

Restrict vault code signing audit exclusion to defaults

Manage which tables are excluded from Vault Code Signing audit tracking to maintain visibility into changes on protected code artifacts.

The *com.glide.codesigning.tables.excluded_from_audit* property lists tables excluded from Vault Code Signing audit tracking. Create, update, and delete operations on these tables don't generate an audit entry, even when a table would otherwise be eligible for Code Signing auditing.

The platform ships this property scoped only to Code Signing's own internal operational tables: certificate storage, crypto module/policy configuration, signing job tracking, and related bookkeeping tables. This prevents the audit noise from internal state changes. Any table name added beyond this default list is also excluded from audit tracking. This property doesn't distinct between an internal housekeeping table and a table containing actual protected, signed code artifacts.

To configure this property:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

1. Navigate to /sys_properties_list.do on the instance.
2. Confirm the *com.glide.codesigning.tables.excluded_from_audit* property either does not exist in the sys_properties table or is set to the following comma-separated list of table names:

```
sys_restricted_caller_access,sys_scope_master,
 sys_kmf_crypto_caller_policy, sys_kmf_crypto_module,
 sn_cse_codesigning_transaction, sn_cse_configuration_property,
 sn_cse_quorum_request,sys_certificate,sysauto_script,
            sys_signing_job,sys_mass_encryption_job
```

More information

Attribute	Description
Configuration name	*com.glide.codesigning.tables.excluded_from_audit*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String (comma-separated table names)
Recommended value	sys_restricted_caller_access,sys_scope_master, sys_kmf_crypto_caller_policy,sys_kmf_crypto_module,sn_cse_codesignir sn_cse_configuration_property, sn_cse_quorum_request,sys_certificate, sysauto_script,sys_signing_job,sys_mass_encryption_job
Default value	sys_restricted_caller_access,sys_scope_master, sys_kmf_crypto_caller_policy, sys_kmf_crypto_module,sn_cse_codesigning_transaction, sn_cse_configuration_property, sn_cse_quorum_request, sys_certificate,sysauto_script, sys_signing_job,sys_mass_encryption_job
Fallback value	sys_restricted_caller_access,sys_scope_master, sys_kmf_crypto_caller_policy,sys_kmf_crypto_module, sn_cse_codesigning_transaction,sn_cse_configuration_property, sn_cse_quorum_request, sys_certificate,sysauto_script, sys_signing_job,sys_mass_encryption_job
Category	Error handling and logging
Security risk	• Security risk rating: Medium • CVSS score: 5.1 • Security risk details: Expanding this list beyond the platform-defined default removes audit visibility for added tables. This can include the very tables that store the protected, signed code artifacts this feature exists to monitor. An administrator or a compromised integration with write access to this property could narrow audit coverage for a specific table without disabling Code Signing auditing overall. This allows the instance

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	to continue to appear fully audited while visibility into changes on that specific table has been silently removed.
Functional impact	Adding a table name to this property stops audit generation for that table's create, update, and delete operations. Removing a table name (or restoring the default list) resumes audit tracking for that table. Changing this property affects only audit trail generation. It has no effect on Code Signing signature validation, enforcement, or the signing mechanism itself. Tables can be excluded from auditing without impacting the signing feature's functionality.
Dependencies and prerequisites	No effect unless both *com.snc.kmf.signature.validation.optin* and *sn_cse.com.snc.csf.vault_audit_enabled* are true.

Track Impersonation Events

Enable impersonation event tracking using a system property.

Use the *glide.audit.track_impersonation* system property to enable the tracking of impersonation events in the Audit [sys_audit] table. When set to `true`, any actions performed via impersonation are recorded as a reference in the sys_audit.user column, providing a clear and traceable audit. When set to `false`, actions performed via impersonation appear to have been performed by the user being impersonated.

Ensure the *glide.audit.track_impersonation* system property exists in the System Properties [sys_properties] table and is set to a value of `true`.

More information

Attribute	Description
Configuration name	*glide.audit.track_impersonation*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	false
Category	Error handling and logging
Security risk	• Severity score: 4.9 • CVSS score: Medium • Security risk details: Tracking impersonation events helps ensure that all actions are traceable to their true originators, reduces the risk of unauthorized changes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	This detailed audit trail helps you meet compliance requirements by providing a clear record of all actions performed via impersonation. The system maintains accountability by ensuring that the true originators of actions are always recorded, even in complex scenarios involving AI agents.
Functional Impact	When enabled, this property ensures that any actions performed via impersonation are accurately recorded as a reference in sys_audit.user column of the Audit [sys_audit] table. If not enabled, any actions performed via impersonation appear to have been performed by the user being impersonated.
Dependencies and prerequisites	None

Turn off verbose SQL error messages for import processor

Configure this property to control whether verbose SQL error messages are displayed.

If the *glide.import.error_message.generic* system property is set to **false** a verbose SQL error message is returned, potentially causing sensitive information disclosure.

Ensure that the *glide.import.error_message.generic* is set to **true** to display a generic error message.

More information

Attribute	Description
Configuration name	*glide.import.error_message.generic*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Error handling and logging
Security risk	• Severity score: 3.1 • CVSS score: Low • Security risk details: If verbose SQL error messages are returned, sensitive information such as database structure, table names, or query details may be exposed. This information can be leveraged by attackers to craft targeted SQL injection attacks or exploit other vulnerabilities, increasing the risk of data breaches and system compromise. Limiting error detail is essential to prevent information disclosure that aids malicious activity.

Attribute	Description
Functional impact	None
Dependencies and prerequisites	None

File and resources

The file and resources category ensures applications handle untrusted file data securely and store untrusted data from untrusted sources with limited permissions in an appropriate location.

This includes controls such as avoiding denial of service through large or unexpected file types, validating file type and preventing against path traversal.

Disallow infected file download

Control whether users can download non-scanned attachments if the antivirus service is down or unreachable.

When the property *com.glide.snap.infected_download_allowed* is set to **true**, users can still download non-scanned attachments if the antivirus service is down or unreachable.

A user may download a malicious file to their desktop.

Set the property *com.glide.snap.infected_download_allowed* to **false**.

More information

Attribute	Description
Configuration name	*com.glide.snap.infected_download_allowed*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	File and resources
Security risk	• Severity score: 6.7 • CVSS score: Medium • Security risk details: A user may download a malicious file to their desktop.
Dependencies and prerequisites	None
Functional impact	Users can download non-scanned attachments if the antivirus service is down or unreachable.

Enable email spam scoring and filtering

Install the Email Filter (*com.glide.email_filter*) plugin to install email filtering within the instance. This filtering identifies existing headers, which enables you to decide what to do with the email based on the associated header. Alternatively, set *com.glide.email_filter* to false.

The Email Filter (*com.glide.email_filter*) plugin installs email filtering within the instance. This filter identifies existing headers, which enables the administrator to decide what to do with the email based on the associated header. The plugin adds a header to each message, which can be used for filtering within the instance. This feature is very helpful for filtering out spam.

Note: Please make sure prerequisite property *glide.email.read.active* is set to **true**, as this control only applies when inbound email is enabled.

Ensure that the plugin *com.glide.email_filter* is activated when the property *glide.email.read.active* is set to **true**.

More information

Attribute	Description
Configuration name	• *com.glide.email_filter* • *glide.email.read.active*
Configuration type	• Plugin (**All** > **System Definition** > **Plugins**) • System Properties (/sys_properties_list.do)
Data type	• Plugin • Boolean
Recommended value	• Plugin is active • true
Default value	<none>
Fallback value	• N/A • true
Category	File and resources
Security risk	• Severity score: 8.1 • CVSS rating: High • Security risk details: Enabling and configuring email filtering is essential for reducing exposure to spam and maintaining system integrity.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	Email is never filtered, blocked, or quarantined from the instance as part of spam scoring. It is only scored and then sent on to the instance. All filtering is done within the instance with the Email Filters plugin.
Dependencies and prerequisites	Before setting this property: Set the *glide.email.read.active* property to true. To learn more, see Enable using your own POP3 server.

Enable antivirus scan

The *com.glide.snap.enable_scan* property activates the antivirus scan functionality.

If *com.glide.snap.enable_scan* isn't set to the recommended value of **true**, then antivirus scanning is disabled.

Set *com.glide.snap.enable_scan* to the recommended value of **true** to enable antivirus scanning.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*com.glide.snap.enable_scan*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	File and resources
Security risk	• Severity score: 7.7 • CVSS rating: High • Security risk details: Users may download malicious files leading to desktop and session compromise.
Functional impact	None
Dependencies and prerequisites	None

Restrict downloadable files types in static content [Updated in Security Center 1.3]

Use the *glide.ui.strict_customer_uploaded_static_content* property to enable restrictions on the file types that can be downloaded when they have been uploaded using the Upload File functionality.

You use this property with the *glide.ui.strict_customer_uploaded_content_types* property, which creates a comma-delimited list of restricted downloadable file types.

Warning: The value for this property is a no DB override. It can't be altered or overridden.

More information

Attribute	Description
Property name	*glide.ui.strict_customer_uploaded_static_content*
Configuration type	System Properties (/sys_properties_list.do)
Category	File and resources
Purpose	To ensure that safe file types are permitted to be downloaded from the application.
Recommended value	true
Default value	true
Security risk rating	3.1
Functional impact	This remediation enforces restriction of file downloads based on the values specified in the *glide.ui.strict_customer_uploaded_content_types* property.
Security risk	(Low) File download restrictions should be applied to any untrusted user input sources.

Limit attachment size in training and prediction flows for GraphQL endpoints [New in Security Center 1.3 and updated in 1.5]

The *glide.platform_ml_di.max_attachment_size_graphql* property controls the maximum allowed size limit for returning attachments in GraphQL endpoints of training or prediction flows.

More information

Attribute	Description
Configuration name	*glide.platform_ml_di.max_attachment_size_graphql*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	5,242,880
Default value	5,242,880

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	File and resources
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: If this property is not set to the recommended value of 5,242,880 or less, then returning large files could cause a denial of service (DoS).
Dependencies and prerequisites	None

Limit attachment size in training and prediction flows [New in Security Center 1.3 and updated in 1.5]

The *glide.platform_ml_di.max_attachment_size* property controls the maximum allowed size limit for returning attachments in training and prediction flows.

More information

Attribute	Description
Configuration name	*glide.platform_ml_di.max_attachment_size*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	4,000,000
Default value	4,000,000
Category	File and resources
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: If *glide.platform_ml_di.max_attachment_size* is not set to the recommended value of 4,000,000 or less, then returning large files could cause a denial of service (DoS) attack.
Dependencies and prerequisites	None

Limit HTTP response body size [New in Security Center 1.3 and updated in 1.5]

Configure the *glide.http.response.get_body.limit.enabled* and *glide.http.response.get_body.limit* properties to protect your instance against *OutOfMemoryExceptions*.

Prevent `OutOfMemoryExceptions` that can result from a request response body being too large using the **glide.http.response.get_body.limit.enabled** and **glide.http.response.get_body.limit** system properties. These exceptions can cause denial of service (DOS) attacks as well as other issues that may aid attackers in compromising an

instance. Not setting these properties to the recommended values could make your instance vulnerable to OutOfMemoryExceptions and denial of service attacks.

To protect your instance against these security vulnerabilities:

- Set the **glide.http.response.get_body.limit.enabled** system property to **true**.
- Ensure that the **glide.http.response.get_body.limit** system property set to no more than 524,288,000 megabytes (500 MB).

More information

Attribute	Description
Configuration name	• **glide.http.response.get_body.limit.enabled** • **glide.http.response.get_body.limit**
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	File and resources
Security risk	• Severity score: 3.1 • Security risk details: Not setting these properties to the recommended values could make your instance vulnerable to *OutOfMemoryExceptions* and denial of service attacks.
Dependencies and prerequisites	None
Functional impact	This property reduces the chances of an *OutOfMemoryException* due to a customer accidentally loading a large file into memory.

Limit maximum number of attachments in email

Configure the number of inbound email attachments allowed per Email [sys_email] record on your instance.

Use the *glide.email.inbound.max_attachment_count* system property to control the maximum number of inbound email attachments allowed per Email [sys_email] record on your instance.

Set the value of this property to **30** or less to help avoid instance performance degradation.

More information

Attribute	Description
Configuration name	*glide.email.inbound.max_attachment_count*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	integer
Recommended value	30 or less
Default value	30
Fallback value	50
Category	File and resources
Security risk	• Severity score: 5.3 • CVSS score: Medium • Security risk details: A large number of attachments in inbound emails can cause instance performance degradation.
Dependencies and prerequisites	None
References	• Email properties • Attachment limit properties

Maximum allowed attachment size

Configure the *com.glide.attachment.max_size* property to control the maximum size (in megabytes) permitted for an uploaded attachment.

The *com.glide.attachment.max_size* system property controls the maximum size of uploaded attachment in megabytes. If the value of property *com.glide.attachment.max_size* is 1024 then the max allowed attachment size is 1Gb.

Note: A real attachment size is calculated through multiplication 1024 * value of the *com.glide.attachment.max_size* property.

Ensure that the property *com.glide.attachment.max_size* is set to `1024` or less.

More information

Attribute	Description
Configuration name	*com.glide.attachment.max_size*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	An integer less than or equal to 1024
Default value	1024
Fallback value	1024
Category	File and resources

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 6.5 • CVSS score: Medium • Security risk details: The platform can accept large files that could fill up storage or cause a denial of service.
Dependencies and prerequisites	None
References	Attachment limit properties

Validate file MIME type in AttachmentCreator web service

The *glide.attachment.enforce_security_validation* property determines whether Multipurpose internet Mail Extensions (MIME) files undergo validation.

Ensure that MIME-types are validated for attachments to prevent dangerous files from being uploaded on your instance using wrong file extensions.

Set the **glide.attachment.enforce_security_validation** system property to **true**. When set to **true**, files are uploaded with the correct file type extension.

More information

Attribute	Description
Configuration name	*glide.attachment.enforce_security_validation*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	File and resources
Security risk	• Severity score: 6.7 • CVSS score: Medium • Security risk details: If the property is set to false, there's no validation for MIME files during uploads. This could enable malicious files to be disguised by changing their file extension.
Dependencies and prerequisites	None
References	https://developer.mozilla.org/en-US/docs/Web/HTTP/Basics_of_HTTP/MIME_types/Common_types
Functional impact	Set this hardening setting to true to run mime-type and file extension validations on uploaded file attachments. No validations are run if this property is set to false. This property is set to true by default.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Validate MIME Type of Attachments from Inbound Emails

Use a system property to validate attachments uploaded from inbound emails.

Set the *glide.security.file.mime_type.validation.inbound_email* system property to **true** to perform MIME type validation on attachments uploaded from inbound emails. Validating the MIME type of uploaded files helps to ensure that the file content matches the expected file format.

Set the system property value to **true** to perform MIME type validation. If the system property is not present on your instance, the fallback value is **false**.

More information

Attribute	Description
Configuration name	*glide.security.file.mime_type.validation.inbound_e*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	false
Category	File and resources
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: If MIME type validation does not occur, users can upload an unexpected type of file to your instance, resulting in potential vulnerabilities where the attachment is handled.
Dependencies and prerequisites	None
Functional impact	Attachments from inbound emails are not uploaded if the MIME type does not validate correctly.

Malicious code

The Malicious Code category ensures that best efforts are made to confirm that your code is free of vulnerabilities and unwanted functionality.

This includes ensuring secure and proper handling for malicious activity, no time based attacks, no outbound communications to untrusted destinations, and that no unauthorized or attacker-controlled code is included. This category includes audit or third party libraries from the application codebase.

Apply static analysis to all users

Configure static analysis to examine scripts from both authenticated and unauthenticated users rather than limiting analysis to guest users only.

By default, static analysis examines all scripts regardless of user authentication status. Setting the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

com.glide.script.static_analysis.only_check_unauthenticated_users property to `true` limits analysis to unauthenticated users only, creating a security gap for authenticated users. Setting the property to `false` confirms comprehensive security coverage across all user types.

To configure this property:

1. Navigate to `/sys_properties_list.do` on the <ph keyref="var.company-no-reg-tm"/> instance.
2. Verify the *com.glide.script.static_analysis.only_check_unauthenticated_users* property is set to `false`.

More information

Attribute	Description
Configuration name	*com.glide.script.static_analysis.only_check_unauthenticated_users*
Configuration type	System Properties (`/sys_properties_list.do`)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Malicious code
Security risk	• Security risk rating: Medium • CVSS score: 6.8 • Security risk details: When this property is set to `true`, static analysis applies only to unauthenticated users, creating significant security gaps: ○ Authenticated users can execute malicious scripts without detection. ○ Insider threats from legitimate users bypass static analysis. ○ Attacks that use stolen credentials or session hijacking avoid analysis. ○ Assumes authenticated users are trusted which may not be valid in all environments. ○ Service accounts and integration users may have elevated privileges but bypass analysis.
Functional impact	Setting this property to `false` brings authenticated-user scripts under static analysis. Existing authenticated-user scripts using patterns like Array.prototype access may trigger security violations. Test critical business rules, script includes, and scheduled jobs before rolling out this property.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Dependencies and prerequisites	The *com.glide.script.static_analysis.disabled* must be set to `false` for the *com.glide.script.static_analysis.only_check_unauthenticated_users* property to have any effect.

Block rooted or jailbroken mobile devices

Secure your instance by preventing unauthorized access from jailbroken devices.

If *glide.sg.allow_rooted_jailbroken_device* is not set to the recommended value of **false**, then the mobile app allows users to use the app from jailbroken or rooted mobile devices. Jailbroken or rooted mobile devices run untrusted code at the system level that can bypass the platform's security model which our mobile apps rely on. Setting *glide.sg.allow_rooted_jailbroken_device* to **false** enables a limited client-side check to display an error message to the user if attempting to use the app from one of these devices.

This configuration maps to MASVS v1.4.2 requirement 8.1 at R-level.

Ensure that the property *glide.sg.allow_rooted_jailbroken_device*is set to **false**.

More information

Attribute	Description
Configuration name	*glide.sg.allow_rooted_jailbroken_device*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Malicious code
Security risk	• Severity score: 4.5 • CVSS score: Medium • Security risk details: Allowing rooted or jailbroken mobile devices significantly increases the risk of credential theft, data leakage, and malicious code execution.
Dependencies and prerequisites	None
References	Access control

Enable Code Signing for application configuration data and scripts [Removed in Security Center 1.3]

Manage Code Signing for application configuration data and scripts on your instance.

Code Signing can help improve security by validating sensitive application configuration data and scripts before they're used. Code Signing creates digital signatures for the data, which are

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

later checked to confirm the authenticity and integrity of the data. This verification helps prevent malicious data or scripts from being used on the instance, which may lead to full compromise of the instance.

Enable Code Signing on your instance by following the steps in Configuring Code Signing. This results in the *com.snc.kmf.signature.validation.flag* system property being set to true.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It's non-revertible.

More information

Attribute	Description
Configuration name	*com.snc.kmf.signature.validation.flag*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Malicious code
Security risk	• Severity score: 6 • CVSS score: Medium • Security risk details: Setting this property to **true** enables Code Signing, which helps improve security by validating sensitive application configuration data and scripts.
Dependencies and prerequisites	None

Enable static analysis

Enable static analysis to provide compile-time security checks for JavaScript code in the scripting sandbox.

When this property is set to `false`, static analysis is enabled and provides compile-time security analysis. When set to `true`, all static analysis security checks are bypassed. This feature allows you to rapidly respond to JavaScript sandbox security exploits.

to configure this property:

1. Navigate to `/sys_properties_list.do` on the ServiceNow instance.
2. Ensure the *com.glide.script.static_analysis.disabled* either doesn't exist or is set to `false`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*com.glide.script.static_analysis.disabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Malicious code
Security risk	• Severity score: 6.8 • CVSS rating: Medium • Security risk details: Disabling static analysis removes protections against sandbox escape attempts that the static analyzer would otherwise detect. While other runtime protections exist in the sandbox, disabling static analysis weakens the overall security posture. Sandbox escapes enables users to execute unauthorized and privileged script.
Functional impact	Depending on the configuration of additional properties, sandbox scripts which match static analysis rules are logged or blocked.
Dependencies and prerequisites	None

Enable synchronous mode for static analysis

The *com.glide.script.static_analysis.enable_sync* property controls whether static analysis security violations block script execution synchronously or are recorded asynchronously. Setting this property to `true` enables synchronous mode, which blocks scripts with security violations.

When set to `false` (the default), violations are recorded asynchronously through statistical logs without preventing script execution. When set to `true`, security violations block script execution with a `SecurityException`. Asynchronous mode (`false`) is for environments where availability is prioritized. Synchronous mode (`true`) is better for high-security environments where blocking malicious scripts is more important than performance.

To configure this property:

- Navigate to `/sys_properties_list.do` on the ServiceNow instance.
- Ensure the property *com.glide.script.static_analysis.enable_sync* exists and is set to `true`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*com.glide.script.static_analysis.enable_sync*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	false
Category	Malicious code
Security risk	• Severity score: 6.8 • CVSS rating: Medium • Security risk details: Setting the *com.glide.script.static_analysis.enable_sync* property to `false` weakens protection against sandbox escape attempts that the static analyzer would otherwise detect when availability or performance is prioritized over security.
Functional impact	This property determines if static analysis security violations block script execution. The default value of `false` records the violation but does not prevent the script execution. Impact of enabling sync mode (false → true): • Every sandbox script execution includes inline static analysis • Scripts with security violations fail with SecurityException • A small amount of latency added to script execution (ranging from microseconds to milliseconds depending on script size) • Violations are persisted to the Error log table Regression testing: • Run load tests to measure performance impact on script-heavy operations • Execute critical business rules, script includes, and background scripts • Check error log (System Log → Errors) for SecurityException records • Monitor response times for pages/APIs that execute sandbox scripts • Review statistics logs for latency percentiles (histogram50ns, histogram90ns, histogram99ns) • Identify any false positives that block legitimate scripts • Test under peak load conditions to ensure acceptable performance

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Dependencies and prerequisites	The property *com.glide.script.static_analysis.disabled* must be set to `false` for the *com.glide.script.static_analysis.enable_sync* property to have any effect.

Enforce signature verification for Flow Designer artifacts

The *com.glide.hub.code_signing.full.validation.enabled* property controls the strictness of checks enforced when Code Signing is fully enabled.

When set to `true`, stricter checks are enforced and certain Flow Designer features incompatible with Code Signing are blocked. If set to `false` or left unset, legacy checks are performed instead, and a subset of Code Signing-incompatible Flow Designer features are allowed to execute.

To configure this property:

1. You must have the security_admin role.
2. The Code Signing plugin (com.glide.code_signing) must be fully enabled. See Configuring Code Signing.
3. Navigate to `/sys_properties_list.do` on the instance.
4. Set the *com.glide.hub.code_signing.full.validation.enabled* property to `true`.

More information

Attribute	Description
Configuration name	*com.glide.hub.code_signing.full.validation.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	`true`
Default value	`false`
Fallback value	`false`
Category	Malicious code
Security risk	• Security risk rating:Medium • CVSS score: 4.4 • When signature validation is turned off, Flow Designer artifacts execute without cryptographic verification of their origin or integrity. This allows attackers to inject unsigned or tampered flows that execute with system privileges. An attacker could modify a flow to exfiltrate data, escalate privileges, or create backdoors without detection because digest validation is bypassed

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	entirely. Disabling this control removes a critical safeguard that verifies only authorized, unmodified code executes through Flow Designer.
Functional impact	When enabled, Flow Designer artifacts are validated for cryptographic signatures and integrity digests. Unsigned or tampered flows are flagged as untrusted in guardrails reports and require explicit review before deployment. When disabled (the default), signature verification and digest validation are skipped, allowing unsigned or tampered flows to execute without verification. Although this reduces scan overhead, it eliminates the detection of unsigned or tampered code. Organizations should enable this property in all production environments to enforce artifact integrity and prevent execution of unverified flows. The default disabled state represents a significant security gap.
Dependencies and prerequisites	This property requires Code Signing to be fully enabled on the instance.

Session management

This category looks at the security of the application state for a user. Sessions should be unique to each individual, unable to be guessed or shared, and invalidated after periods of inactivity or when not required. This includes factors such as cookie attributes for cookie-based sessions, session token generation, and storage and requirements for federated re-authentication.

Apply continuous authentication policies to mobile sessions

Reduce the risk of session hijacking by applying continuous authentication policies to mobile sessions.

Ensure that mobile users are using the high assurance session feature of the Zero Trust - Continuous Authentication plugin by setting the **glide.zta.high_assurance.mobile.session.allowed** system property to **false**. To bypass continuous authentication policies for mobile sessions, set this property to **true**.

Set the **glide.zta.high_assurance.mobile.session.allowed** system property to **false**. This action decreases the risk of session hijacking and persistent access if a session is compromised. If this property doesn't appear in the System Properties [sys_properties] table, the default value is **false**.

More information

Attribute	Description
Technical configuration name	glide.zta.high_assurance.mobile.session.allowed
Plugin applicability	Zero Trust - Continuous Authentication (com.snc.zero_trust_continuous_authentication)
Security risk	If this system property set to **true**, the high assurance session feature isn't applied to mobile sessions. Reauthentication doesn't happen as defined in policies for high role sessions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	This increases the risk of session hijacking and persistent access if a session is compromised.
Common Vulnerability Scoring System (CVSS) score	3.9
Common Vulnerability Scoring System (CVSS) rating	Low
Functional impact	If set to **true**, the high assurance session feature doesn't apply to mobile sessions, which increases the risk of session hijacking and persistent access if a session is compromised.
Dependencies and prerequisites	None
Data type	Boolean
Base system value	false
Fallback value	false
Recommended value	false

To learn more about adding or creating a system property, see Add a system property.

Minimize absolute session timeout duration

Use the *glide.ui.user_cookie.max_life_span_in_days* property to set a maximum life span for user cookies created when users log in with the **Remember Me** checkbox selected. When the cookie expires, users who have selected the **Remember Me** checkbox are forced to reauthenticate into the instance.

If the *glide.ui.user_cookie.max_life_span_in_days* system property is not set to the recommended value of 30 or other appropriate value, then a very long life session could be more vulnerable to session hijack attacks.

Ensure that the property *glide.ui.user_cookie.max_life_span_in_days* is set to 30 or less.

Note: To enforce a maximum session time for any active user sessions, see Managing user sessions.

More information

Attribute	Description
Configuration name	*glide.ui.user_cookie.max_life_span_in_days*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	30 or less
Default value	30
Fallback value	30
Category	Session management

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 4.2 • CVSS rating: Medium • Security risk details: A long session lifespan extends the window of opportunity for attackers to hijack active sessions, increasing the likelihood of unauthorized access if credentials or session tokens are compromised.
Functional impact	This property enforces mandatory re-login by avoiding any sort of cookie rotation after a given time frame.
Dependencies and prerequisites	None

Define active session timeout exception roles

Use a system property to exempt roles from active session timeout limits.

Use the *glide.active.session.timeout.exception.roles* system property to exempt roles from an active session timeout limit. The active session timeout feature helps ensure that a hijacked session cannot be used indefinitely without providing authentication information. It is best practice to only consider an active session timeout limit exception for internal integration account roles.

Configure the *glide.active.session.timeout.exception.roles* property to roles which must be exempt from active session timeouts. This property value is a comma separated list of roles. The default value is `edge_encryption,mid_server,maint`.

More information

Attribute	Description
Configuration name	*glide.active.session.timeout.exception.roles*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	edge_encryption,mid_server,maint
Default value	edge_encryption,mid_server,maint
Fallback value	edge_encryption,mid_server,maint
Category	Session management
Security risk	• Severity score: 6.4 • CVSS score: Medium • Consider an active session timeout limit exception only for internal integration account roles. If a user is a victim of a session hijacking attempt, and has a role with an exception, attackers using that session can continue to authenticate to that session indefinitely.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	This may increase the impact of a security incident by enabling an attacker more time to make use of a hijacked account.
Dependencies and prerequisites	None

Enable UserCookie version 3.1

Manage the version of UserCookie that is enabled on your instance to secure the storage of the secret key in the source code.

UserCookie v3 is generated only when property *glide.ui.secure.cookies.use_kmf is disabled* is disabled. UserCookie v3 is not secure due to storing secret key for HMAC in source code and identical for all customers. By setting the property *glide.ui.secure.cookies.use_kmf* to **true**, UserCookie v3.1 is used and secret key is stored in security storage such as KMF.

More information

Attribute	Description
Configuration name	*glide.ui.secure.cookies.use_kmf*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Session management
Security risk	• Severity score: 7.1 • CVSS score: High • Security risk details: This creates a significant risk of session hijacking, as attackers who obtain or reverse-engineer the key can forge authentication cookies and impersonate users.
Dependencies and prerequisites	None

Enforce password reset on API requests

Manage how the password reset functionality operates on your instance.

When a user is marked for Password needs reset they must provide a new password at the next authentication attempt. The *glide.authenticate.api.user.reset_password.mandatory* system property controls whether the password reset is mandatory before making API calls. If *glide.authenticate.api.user.reset_password.mandatory* isn't set to the recommended value of **true**, then user accounts marked as Password needs reset can still perform most common operations by querying the table API through basic authentication.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Ensure the property *glide.authenticate.api.user.reset_password.mandatory* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.authenticate.api.user.reset_password.mandato*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Session management
Security risk	• Severity score: 8.1 • CVSS score: High • Security risk details: This could allow information disclosure in the event that stale accounts are compromised.
Dependencies and prerequisites	None

Enable HTTP Only Cookie Flag

Use the *glide.cookies.http_only* property to enable the HTTPOnly attribute for sensitive cookies.

If the *glide.cookies.http_only* system property is not set to the recommended value of **true**, then the instance does not require the HTTPOnly attribute for sensitive cookies.

Ensure that the property *glide.cookies.http_only* is set to **true**.

⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.cookies.http_only*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Session management

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 8.0 • CVSS rating: High • Security risk details: The HTTPOnly attribute is used to prevent attacks, such as cross-site scripting, because it doesn't allow access to the cookie using a client-side script, such as JavaScript.
Functional impact	None
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Enable MID Server governance checks

Use an inactivity timeout on your MID Servers to reduce exposure to potential attackers.

Unused MID Servers that remain active create bidirectional security risk. Their credentials can still authenticate to the ServiceNow instance, giving an attacker a valid entry point. While active, the instance can still issue commands to them, extending the attack surface of instance compromise into infrastructure no one is monitoring.

With MID Server governance you can keep track of the last usage of each MID Server and create a policy to decommission it after a period of inactivity. The default inactivity timeout for MID Servers is 30 days.

Confirm that the *mid.inactivity.timeout.enabled* property exists in the System Properties [sys_properties] table and is set to **true**.

More information

Attribute	Description
Configuration name	*mid.inactivity.timeout.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Session management
Security risk	• Severity score: 4.6 • CVSS rating: Medium • Security risk details: An attacker with access to an active MID Server could compromise the credential or impersonate the server and add output records to the ECC queue. An attacker wouldn't be able to use these credentials to horizontally traverse to other MID

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	servers by inserting commands for them inside of ECC queue due to role restrictions on each MID Server user.
Functional impact	Inactive MID Servers are decommissioned on purpose.
Dependencies and prerequisites	None

Invalidate Session After OAuth Token Expiration [New in Security Center 2.0]

Use a system property to the secure value to prevent users from continuing to use a session via cookies after the OAuth token used to create the session expires.

When an OAuth access token is issued, the response includes a cookie. Users can use this cookie to continue using a session even after the OAuth token used to create that session expires. Use the *`glide.authenticate.oauth.post.token.expiration.cookie_auth.disabled`* system property to prevent this.

Ensure the **glide.authenticate.oauth.post.token.expiration.cookie_auth.disabled** system property exists in the System Properties [sys_properties] table, and is set to a value of `true`.

More information

Attribute	Description
Configuration name	*`glide.authenticate.oauth.post.token.expiration.coo`*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Session management
Security risk	• Severity score: 6.8 • CVSS score: Medium • Security risk details: If an OAuth token is leaked or compromised, the lack of expiration would allow an attacker to use and extend the session via the created cookie. Malicious users can use sessions to access unauthorized resources and take unauthorized actions. Set this property to the secure value to eliminate this hidden session extension mechanism and reduce replay risk by enforcing token expiration.
Dependencies and prerequisites	None
Functional impact	Impact when set to true:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Sessions end immediately when the access token expires. • Cookies no longer refresh session validity. • Clients must use refresh tokens or re-authenticate to obtain a new access token. Potential Breakage: • Legacy clients or custom integrations relying on cookie-based session extension fail after token expiry. • Long-running jobs without token renewal logic may encounter 401 errors. What Continues to Work: • Standard OAuth flows with refresh tokens. • Properly designed integrations that renew tokens proactively.

Minimize concurrent interactive session quantity [Updated in Security Center 1.3]

Use this property with the Limit Concurrent Sessions plugin to control the number of active sessions that can be opened by a user.

Use the **Glide Authenticate Max Concurrent Interactive Sessions** property with the **Limit Concurrent Session** (*com.glide.limit.concurrent.sessions*) plugin to control the number of active sessions opened for a user. The recommended value is **1**, which reduces the number of sessions opened (a greater number increases the likelihood that a session could be hijacked).

More information

Attribute	Description
Configuration name	*glide.authenticate.max.concurrent.interactive.sess*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	1
Default value	1
Category	Session management
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: Setting the default value of the property greater than 1 increases the chance of session hijacking.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Dependencies and prerequisites	The **Concurrent Interactive Sessions** (*com.glide.limit.concurrent.sessions*) plugin should be active.
References	Limit concurrent sessions

Limit concurrent sessions across all nodes

Use the *glide.authenticate.limit.concurrent.sessions.across.all.nodes* property with the Limit Concurrent Sessions plugin to manage the number of sessions tracked across all nodes.

The *glide.authenticate.limit.concurrent.sessions.across.all.nodes* system property is meant to be used with the Limit Concurrent Sessions plugin (com.glide.limit.concurrent.sessions) plugin. When this plugin is installed and configured, the number of open sessions can be limited per user. When this property is set, the number of sessions will be tracked across all nodes instead of a single application nodes.

Ensure that the *glide.authenticate.limit.concurrent.sessions.across.all.nodes* sysem property is set to **true** when the Limit Concurrent Sessions plugin (com.glide.limit.concurrent.sessions) plugin is active.

More information

Attribute	Description
Configuration name	*glide.authenticate.limit.concurrent.sessions.acros*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Session management
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: If this property is not set to true, multiple sessions can be open across multiple nodes, increasing the likelihood of a successful session hijacking.
Dependencies and prerequisites	None
References	Limit concurrent sessions

Activate Limit Concurrent Sessions Plugin

Configure the com.glide.limit.concurrent.sessions plugin to reduce the chance of session hijacking on your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The Limit Concurrent Sessions plugin (com.glide.limit.concurrent.sessions) allows an administrator to limit the number of active sessions per user/role. It is recommended this plugin be enabled and configured to reduce the likelihood of session hijacking. If this plugin is enabled and configured, there will be a limit to the number of open sessions that can be hijacked.

More information

Attribute	Description
Configuration name	• *com.glide.limit.concurrent.sessions* (plugin) • *glide.authenticate.limit.concurrent.interactive.* property) • *glide.authenticate.max.concurrent.interactive.se* property)
Configuration type	System Properties (/sys_properties_list.do)
Data type	• plugin • system property (Boolean) • system property (Integer) plugin
Recommended value	• *com.glide.limit.concurrent.sessions* is enabled • *glide.authenticate.limit.concurrent.interactive.* system property set to **true** • *glide.authenticate.max.concurrent.interactive.se* set to a numeric value depending on the needs of your organization.
Default value	None
Category	Session management
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: Higher numbers of active concurrent sessions creates security risk by increasing the attack surface for account compromise, making it harder to detect unauthorized access and enforce session accountability across devices and locations.
Dependencies and prerequisites	None

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Limit guest's active session life span

Use the *glide.guest.active.session.life_span* property to control the duration of an active guest's HTTP sessions.

The *glide.guest.active.session.life_span* property enforces a maximum lifespan on active guest HTTP sessions, regardless of the session activity. The configured value is in minutes. A value of zero disables the lifespan limit entirely, allowing sessions to persist indefinitely until the inactive timeout fires. Guest users are unauthenticated users who access the instance without logging in.

A larger maximum lifespan allows an attacker to persist a stolen session for longer, increasing the scope of a security incident.

Navigate to /sys_properties_list.do on the instance and verify that the *glide.guest.active.session.life_span* property exists and is set to a value greater than 0 and less than or equal to 720 minutes.

More information

Attribute	Description
Configuration name	*glide.guest.active.session.life_span*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	720
Default value	0
Fallback value	0
Category	Session management
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: A larger maximum lifespan allows an attacker to persist a stolen session for longer, increasing the scope of a security incident.
Functional impact	Guest HTTP sessions that exceed the configured lifespan are silently invalidated and reissued a new session ID. The guest user sees no error or logout screen, but any session-scoped state (for example, in-progress form data, embedded portal widget context, or session-based rate limiting) accumulated during that session is lost and starts fresh. Legitimate guest users on long-running but otherwise idle browser tabs require reloading the page after the configured interval elapses.
Dependencies and prerequisites	This control interacts with the *glide.guest.session_timeout* property, which controls the guest idle-session timeout duration. The platform requires the active session maximum lifespan to be greater than or equal to the idle timeout. If the active session lifespan is configured to a value lower

Attribute	Description
	than the idle-session timeout, the platform automatically increases the effective lifespan to match the idle-session timeout and logs a warning message.

Minimize Concurrent Interactive Sessions with Limit Concurrent Sessions Plugin

Manage the number of interactive sessions on your instance.

The *glide.authenticate.limit.concurrent.interactive.sessions* system property controls the number of active sessions that can be open for a user when the Limit Concurrent Sessions (com.glide.limit.concurrent.sessions) plugin is enabled. It is recommended that this value be the default of `1` to reduce the number of sessions that can be left open for a user.

Ensure that the property *glide.authenticate.limit.concurrent.interactive.sessions* is set to `1` when the Limit Concurrent Sessions (com.glide.limit.concurrent.sessions) plugin is active.

More information

Attribute	Description
Configuration name	*glide.authenticate.limit.concurrent.interactive.se*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	1
Default value	<none>
Fallback value	1
Category	Session management
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: A greater number of open sessions means there are more sessions that can potentially be hijacked.
Dependencies and prerequisites	None
References	Minimize Concurrent Interactive Sessions with Limit Concurrent Sessions Plugin

Limit integrations' active session life span

Use the *glide.integrations.active.session.life_span* property to enforce the maximum lifespan on active integration HTTP sessions, regardless of session inactivity.

The configured value is in minutes. A value of zero disables the lifespan limit entirely, allowing sessions to persist indefinitely until the inactive timeout fires. This particular property is limited to integrations that have low-privilege access to an instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

A larger maximum lifespan allows an attacker to persist a stolen session for longer, increasing the scope of a security incident.

To configure the *glide.integrations.active.session.life_span* propeerty:

1. Navigate to /sys_properties_list.do on the instance.
2. Ensure the *glide.integrations.active.session.life_span* property exists and is set to a value greater than 0 and less than or equal to 720 minutes.

More information

Attribute	Description
Configuration name	*glide.integrations.active.session.life_span*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	Between 1 and 720
Default value	0
Fallback value	0
Category	Session management
Security risk	• Severity score: 4.2 • CVSS rating: Medium • Security risk details: A larger maximum lifespan allows an attacker to persist a stolen session for longer, increasing the scope of a security incident.
Functional impact	Integration sessions that exceed the configured lifespan are silently invalidated and reissued a new session ID. The integration user sees no error, but any session-scoped state accumulated during that session is lost and starts fresh.
Dependencies and prerequisites	This control interacts with the *glide.integration.session_timeout* property, which controls the integration idle-session timeout duration. The platform requires the active session maximum lifespan to be greater than or equal to the integration idle timeout. If the active session lifespan is configured lower than the idle-session timeout, the platform automatically increases the effective lifespan to match the idle-session timeout. The platform logs a warning message when this occurs.

Limit the policy-based mobile refresh token interval

Use the *glide.authenticate.session_access.mobile.refresh_token_interval* property to govern the length of time that must elapse before a mobile device user will be forced to re-authenticate.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The *glide.authenticate.session_access.mobile.refresh_token_interval* system property governs the length of time after which a mobile device user will be forced to re-authenticate. This only applies if the admin has configured the Identity Provider attributes (which can vary for each login) in the session access policy and the user authenticates via Single Sign On (SSO). The property value is an integer in seconds. The recommended value is `1800` (30 minutes).

Ensure that the *glide.authenticate.session_access.mobile.refresh_token_interval* property is set to a value of `1800` or below.

More information

Attribute	Description
Configuration name	*glide.authenticate.session_access.mobile.refresh_t*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	An integer less than or equal to 1800
Default value	1800
Fallback value	1800
Category	Session management
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: A large value may grant a larger time frame for session access to be hijacked by an attacker.
Dependencies and prerequisites	Zero trust: Policy-based session access
Functional impact	This setting governs the post-login timeout for mobile SSO users. Users are logged out if the admin has configured Identity provider attributes in the session access policy.

Limit UI active session life span

The *glide.ui.active.session.life_span* property enforces max lifespan on active authenticated HTTP sessions irrespective of inactive timeout.

The *glide.ui.active.session.life_span* property enforces a maximum lifespan on active, authenticated UI HTTP sessions, regardless of session inactivity. The configured value is in minutes. A value of zero disables the lifespan limit entirely, allowing sessions to persist indefinitely until the inactive timeout fires. This particular property is limited to authenticated end users accessing the instance through the UI.

Navigate to /sys_properties_list.do on the instance. Ensure the *glide.ui.active.session.life_span* property exists and is set to a value greater than 0 and less than or equal to 720 minutes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.ui.active.session.life_span*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	1-720
Default value	0
Fallback value	0
Category	Session management
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: A larger maximum lifespan allows an attacker to persist a stolen session for longer, increasing the scope of a security incident.
Functional impact	Authenticated UI sessions that exceed the configured lifespan are explicitly logged out. The session cookies are cleared and the session is invalidated, forcing the user to re-authenticate, rather than silently reissuing a new session ID as occurs with guest and integration sessions. Users must re-authenticate to continue working, even if they were actively using the platform when the session expired.
Dependencies and prerequisites	This control interacts with the *glide.ui.session_timeout* property, which controls the UI idle-session timeout duration. The platform requires the active session maximum lifespan to be greater than or equal to the idle timeout. If the active session lifespan is configured to a value lower than the idle-session timeout, the platform automatically increases the effective lifespan to match the idle-session timeout and logs a warning message.

Limit session length for high assurance sessions

Reduce the risk of account takeover in high assurance sessions by limiting session length

Reduce the risk of account takeover in high assurance sessions by limiting the length of the session. After the specified length of time, end-users must re-authenticate.

Use the **glide.zta.high_assurance.session.timeout** system property to set a time, in minutes, after which users must re-authenticate. The value of this property must be between 1 and 480 minutes. Consider limiting this value to 30 or lower to reduce the risk of account takeover.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Technical configuration name	glide.zta.high_assurance.session.timeout
Plugin applicability	Zero Trust - Continuous Authentication (com.snc.zero_trust_continuous_authentication)
Security risk	Shorter session lengths reduce the risk of account takeover by forcing users to re-authenticate.
Common Vulnerability Scoring System (CVSS) score	3.3
Common Vulnerability Scoring System (CVSS) rating	Low
Functional impact	Users in high assurance sessions must re-authenticate at the interval set by this property.
Dependencies and prerequisites	None
Data type	Integer
Base system value	30
Fallback value	30
Recommended value	30 or lower

To learn more about adding or creating a system property, see Add a system property.

Proactively invalidate sessions after defined durations

The *glide.active.session.timeout.invalidate.session* property controls whether a timed-out session is proactively invalidated before the Tomcat server processes it.

When this property value isn't set to **true**, there's a brief interval where the application doesn't proactively invalidates the timed-out session before the Tomcat container invalidates it. To enable active session timeout, the user also needs to define at least one of the following session timeout properties:

Property	Description
glide.ui.active.session.life_span	Defines the timeout period (in minutes) for UI sessions.
glide.guest.active.session.life_span	Defines the timeout period (in minutes) for guest sessions.
glide.integrations.active.session.life_span	Defines the timeout period (in minutes) for integration sessions.

Ensure that the property *glide.active.session.timeout.invalidate.session* is set to true.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	• *glide.active.session.timeout.invalidate.session* • *glide.ui.active.session.life_span* • *glide.guest.active.session.life_span* • *glide.integrations.active.session.life_span*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	false
Category	Session management
Security risk	• Severity score: 4.6 • CVSS score: Medium • Security risk details: If a session is hijacked, an attacker may be able to use a session during this small period.
Dependencies and prerequisites	None

Require JWT trust verification for guest embedded sessions

The *glide.embedded.session.trust.verification.enabled* property determines whether guest embeddable sessions require JSON Web Tokens (JWT) validation for third-party origin verification.

This property requires JWT validation to confirm that guest embeddable session requests come from trusted third-party websites.

To configure this property:

1. Navigate to `/sys_properties_list.do` on the instance.
2. Verify *glide.embedded.session.trust.verification.enabled* exists and is set to **true**.

More information

Attribute	Description
Configuration name	*glide.embedded.session.trust.verification.enabled*
Configuration type	System Properties (`/sys_properties_list.do`)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Session management
Security risk	• Severity score: 5.3 • CVSS rating: Medium • Security risk details: When this property is inactive, the platform establishes guest embedded sessions for Web embeddables components without JWT verification. The JWT is designed to confirm that requests originate from trusted third party websites.
Functional impact	When enabled, any third-party website embedding guest components must implement the JWT-based token callback in its global code. See the Web embeddables guest user documentation for more details. Sites that follow the documented setup are unaffected. JWT verification is the default behavior for this feature. Sites relying on the undocumented fallback behavior (proceeding without a token) must implement the callback before its embedded guest sessions can be established once enforcement begins.
Dependencies and prerequisites	Only applicable when the web components for guest embeddables (com.sn_guest_components) plugin is active. This property has no effect, and this control does not evaluate it, on instances where the plugin is not installed and active.

Rotate HTTP session identifiers

Use the *glide.ui.rotate_sessions* property to enable rotation of the HTTP session identifiers to reduce security vulnerabilities.

If the *glide.ui.rotate_sessions* system property is not set to the recommended value of **true**, then identifying information on a session is kept and not rotated between applications.

Ensure that the property *glide.ui.rotate_sessions* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.ui.rotate_sessions*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Default value	true
Fallback value	true
Category	Session management
Security risk	• Severity score: 8.8 • CVSS rating: High • Security risk details: Not setting *glide.ui.rotate_sessions* system property to the recommended value of **true** increases the risk of session hijacking, as attackers could reuse session identifiers to gain unauthorized access.
Functional impact	This remediation modified the SessionID when user navigates from unauthenticated page to authenticated pages. • If you are using a proxy or hardcoding the SessionID when a user first logs in, or for any purpose, then there can be a potential functionality impact. • If you are using the SAML 2.0 plugin for Single Sign-on authentication, it might interfere with the session information sharing between the instance and the Identity Provider. In such case, you can set this property to false.
Dependencies and prerequisites	None

Minimize concurrent interactive session quantity [Updated in Security Center 1.3]

Use this property with the Limit Concurrent Sessions plugin to control the number of active sessions that can be opened by a user.

Use the **Glide Authenticate Max Concurrent Interactive Sessions** property with the **Limit Concurrent Session** (*com.glide.limit.concurrent.sessions*) plugin to control the number of active sessions opened for a user. The recommended value is **1**, which reduces the number of sessions opened (a greater number increases the likelihood that a session could be hijacked).

More information

Attribute	Description
Configuration name	*glide.authenticate.max.concurrent.interactive.sess*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	1
Default value	1

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Session management
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: Setting the default value of the property greater than 1 increases the chance of session hijacking.
Dependencies and prerequisites	The **Concurrent Interactive Sessions** (*com.glide.limit.concurrent.sessions*) plugin should be active.
References	Limit concurrent sessions

Minimize session activity timeout duration

Use the *glide.ui.session_timeout* property to set the session activity timeout duration in minutes.

The *glide.ui.session_timeout* property controls the inactive session timeout for authenticated users, specified in minutes. If this property is not set to the recommended value of 30 minutes or less, the session may remain valid for extended periods without user activity.

A long session timeout allows inactive sessions to remain valid for extended periods, increasing the chance that an attacker could hijack the session before it expires.

To configure the *glide.ui.session_timeout* property:

1. Navigate to /sys_properties_list.do on the instance.
2. Confirm the *glide.ui.session_timeout* property doesn't exist in the sys_properties table or is set to 30 minutes or less.

More information

Attribute	Description
Configuration name	*glide.ui.session_timeout*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	30 or less
Default value	30
Fallback value	30
Category	Session management
Security risk	• Severity score: 7.5 • CVSS rating: High

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Security risk details: A long session timeout allows inactive sessions to remain valid for extended periods, increasing the chance that an attacker could hijack the session before it expires.
Functional impact	Reducing the *glide.ui.session_timeout* property lowers the amount of idle time allowed before a user's session ends automatically, requiring re-authentication. Users who leave a session idle longer than the configured value (for example, while completing a long form, waiting on an approval, or stepping away between tasks) will be logged out and must sign in again. Administrators should verify that long-running interactive workflows still complete comfortably within the new timeout window. They should also confirm that any automation or integration currently relying on a long-lived interactive UI sessions is migrated to a dedicated authentication method. Use OAuth or a service account rather than depending on session longevity.
Dependencies and prerequisites	The *glide.ui.session_timeout* property is capped by the static property *glide.ui.max_session_timeout*, which limits the maximum effective value to 1440 minutes.

Minimize session window timeout duration

Use the *glide.ui.user_cookie.life_span_in_days* property to set the expiration time period for the Remember Me cookie. The default value is 15 days and the maximum cap is at 30 days.

The *glide.ui.user_cookie.life_span_in_days* system property affects the expiry of cookies. After each successful authentication, the cookie will expire after the number of days specified as the property value. If *glide.ui.user_cookie.life_span_in_days* isn't set to the recommended value of `15` or less, then there is a higher risk that the cookie, if stolen, can be used for longer.

Ensure the property *glide.ui.user_cookie.life_span_in_days* is set to `15` or less.

More information

Attribute	Description
Configuration name	*glide.ui.user_cookie.life_span_in_days*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	15 or less
Default value	15

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Fallback value	15
Category	Session management
Security risk	• Severity score: 4.9 • CVSS rating: Medium • Security risk details: A longer life span increases the time window that a stolen cookie can be used.
Functional impact	This property is enabled by the end user when the end user checks the **Remember me** check box from the login page and logs in to the ServiceNow AI Platform.
Dependencies and prerequisites	None

Stored cryptography

This category focuses on the encryption of stored data. It encompasses several key aspects, such as employing established algorithms and cryptographic modules, ensuring the proper generation of pseudo-random values, implementing encryption based on data classification, and securely storing and isolating key material.

Enable glide KMF encrypter [Removed in Security Center 1.3.2]

Manage the encrypters used for Password2 fields on your instance.

Use the *glide.kmf.encrypter.enabled* property to set KMF encrypter as the default encrypter for Password2 fields. This property ensures that strong and compliant encryption standards are being used instead of a legacy encrypter. To ensure that KMF encrypter is used instead of the legacy encrypter, set this property to **true**.

More information

Attribute	Description
Configuration name	*glide.kmf.encrypter.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Stored cryptography
Security risk	• Severity score: 4.9 • CVSS score: Medium • Security risk details: Setting this property to **true** ensures that KMF encrypter is being used instead of legacy encrypter.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
References	Password2 encryption with the Key Management Framework (KMF)

Disable use of TripleDES/3DES encryption algorithm

Avoid the security risks of outdated encryption methods by disabling the use of the TripleDES/3DES encryption algorithm.

Disable the use of legacy, deprecated Triple Data Encryption Standard (3DES or Triple-DES) on your instance, which may lead to loss and leakage of sensitive information.

The National Institute of Standards and Technology (NIST) has advised against using Triple DES (3DES) to encrypt data. For more details, refer to NIST 800-131A Rev 2.#3DES is now banned for encryption in federal systems. Going forward, TDES can only be used for historical purposes, such as decrypting old messages, key unwrapping, and MAC verification.

The **glide.security.3des.encryption.allow** system property controls whether 3DES encryption is enabled on your instance, however there are several steps which may need to be taken to verify that your instance is ready for deprecation. Review KB1704481 for further information on the deprecation process before setting this property.

More information

Attribute	Description
Technical configuration name	glide.security.3des.encryption.allow
Plugin applicability	None
Security risk	Usage of outdated and weak encryption like 3DES may lead to loss and leakage of sensitive information.
Common Vulnerability Scoring System (CVSS) score	4.2
Common Vulnerability Scoring System (CVSS) rating	Medium
Functional impact	Setting this property to **false** helps prevent your instance from use of outdated and weak encryption. This affects how Password2 data is stored. Review KB1704481 for further information on functional impact of 3DES deprecation.
Dependencies and prerequisites	Perform the tasks outlined in KB1704481 before changing the value of this property.
Data type	Boolean
Base system value	false
Fallback value	false
Recommended value	false

To learn more about adding or creating a system property, see Add a system property.

Prevent usage of 3DES keys

Disable the use of 3DES static keys on your instance with a system property.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Use the *glide.security.3des.static_keys_usable* system property to disable the usage of 3DES static keys on your instance. This property should be set automatically by a scheduled job, the status of which can be checked via the property *glide.security.3des.removal_job_status*. In cases where this property isn't configured to **false**, after the scheduled job runs and the status is KEYS_DEACTIVATED, the scheduled job waits until this property is configured to **false** before proceeding with deletion of the 3DES static keys.

Ensure the *glide.security.3des.static_keys_usable* exists on the System Properties [sys_properties] table and is set to a value of **false**. Review KB1704481 for further information on 3DES deprecation.

More information

Attribute	Description
Configuration name	*glide.security.3des.static_keys_usable*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	true
Fallback value	true
Category	Stored cryptography
Security risk	• Severity score: 5 • CVSS score: Medium • 3DES is deprecated, and the use of 3DES and 3DES static keys outside of temporary backwards compatibility isn't recommended. Continued use may lead to situations of sensitive information disclosure if a user were to obtain access to encrypted data.
Functional impact	When set to **false**, there may be unlikely situations where code and data residing on the instance still relied on by 3DES static keys are now inaccessible.
Dependencies and prerequisites	The property *glide.security.3des.removal_job_status* acts as a readiness gate. The scheduled job walks through deactivating/rotating out old 3DES static keys, and that job reports its progress via this status property. Until that job reports it's done (KEYS_DEACTIVATED or RESUPPLIED), it's not yet possible to flip *glide.security.3des.static_keys_usable* to **false**, because doing so prematurely could break decryption of data still encrypted with those static keys.

To learn more about adding or creating a system property, see Add a system property.

Validation, sanitization, and encoding

Validation, sanitization, and encoding addresses input validation to prevent against vulnerabilities like Cross-Site Scripting (XSS), SQL injection and other attacks.

This control ensures input validation and output encoding are in place and correctly configured, such as encoding or escaping output data. This category also includes checks for items such as deserialization of objects and positive validation through allow lists.

Allow HTML Links to Trusted Domains in the Description Fields of the Impact Workspace Module [New in Security Center 7.0]

Use a system property to help sanitize the HTML allowed in the descriptions fields. This property limits the allowed links to only those from the trusted domains listed in the property.

Note: This hardening setting is not a part of the hardening baseline. It does not appear in Security Center hardening pages and affect your hardening score.

The Impact Workspace module allows HTML in a number of description-related fields. When configured, the *sn_impact_common.whitelisted.url_HTML_injection* system property contains a comma-separated list of domain names. Description fields for the Impact Workspace module are allowed to contain HREFs with URLs only from the domains listed in the property.

Ensure the *sn_impact_common.whitelisted.url_HTML_injection* system property is set to a comma-separated list of domain names that represent the domains allowed in HTTP reference URLs of description fields for the Impact Workspace module.

To disallow HREFs in these fields, set the property to an empty string. If the property doesn't exist on the System Properties [sys_properties] table, it defaults to this list: `servicenow.com, service-now.com, youtube.com, google.com, youtu.be, soti.net, dpdhl.sharepoint.com, documentation.avaya.com, www.juniper.net, servicenow.sharepoint.com, servicenow-my.sharepoint.com, scaledagileframework.com`.

More information

Attribute	Description
Configuration name	*sn_impact_common.whitelisted.url_HTML_injection*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String list
Recommended value	servicenow.com, service-now.com, youtube.com, google.com, youtu.be, soti.net, dpdhl.sharepoint.com, documentation.avaya.com, www.juniper.net, servicenow.sharepoint.com, servicenow-my.sharepoint.com, scaledagileframework.com
Default value	servicenow.com, service-now.com, youtube.com, google.com, youtu.be, soti.net, dpdhl.sharepoint.com, documentation.avaya.com, www.juniper.net, servicenow.sharepoint.com, servicenow-my.sharepoint.com, scaledagileframework.com
Fallback value	servicenow.com, service-now.com, youtube.com, google.com, youtu.be, soti.net, dpdhl.sharepoint.com,

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	documentation.avaya.com, www.juniper.net, servicenow.sharepoint.com, servicenow-my.sharepoint.com, scaledagileframework.com
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 4.4 • CVSS score: Medium • If an untrusted domain is added to the property, this opens these fields up to containing links to risky sources which can lead HTML injection attacks. The exact risk is dependent on the customer instance.
Functional impact	If the property is empty, no HREFs are allowed in the field text and all HREFs are removed. Any links using domains not listed in the property are removed. An improper value for this field could result in corrupted data for the affected fields.
Dependencies and prerequisites	If the *sn_impact_common.blacklist_tags_HTML_injection* system property contains HTML tags that surround HREF links, then all links within those tags will be removed.

To learn more about adding or creating a system property, see Add a system property.

Enable the hardened java security manager

The *glide.security.manager* property contains the Java classname of the current Java security manager.

The *glide.security.manager* system property contains Java classname of current Java security manager. ServiceNow has standardized on the Contextual Security Manager. If *glide.security.manager* is not set to the recommended value of `com.glide.sys.security.ContextualSecurityManager`, then the instance may be using an obsolete Java security manager, which is missing expected hardening policies.

Ensure the property *glide.security.manager* is set to `com.glide.sys.security.ContextualSecurityManager`.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.security.manager*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	com.glide.sys.security.ContextualSecurityManager
Default value	com.glide.sys.security.ContextualSecurityManager

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Fallback value	com.glide.sys.security.ContextualSecurityManager
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 7.2 • CVSS score: High • Security risk details:Without this hardening, it may be possible for a malicious actor with script execution access to achieve remote code execution on the instance.
Dependencies and prerequisites	None

Enable HTML Sanitizer [Updated in Security Center 1.3]

Use the *glide.html.sanitize_all_fields* property to enable the HTMLSanitizer script include, which sanitizes HTML input based on exclusion listed and inclusion listed attributes configured in a script.

The field types available with dictionary/fields include HTML and Translated HTML. These HTML input fields enable users to write HTML formatted input, for example:

`<h1>Test</h1>`, using the most basic HTML tags such as `<img>`, `<a href ...>`, and `<iframe>`.

It can open a door for a malicious attacker to inject malicious vector with HTML tags such as:

```
[<IMG SRC=" &#14; JavaScript:alert('XSS');">][<IMG
onmouseover="alert('xss')">],[a href="" onclick=alert(/xss/)].
```

More information

Attribute	Description
Property name	*glide.html.sanitize_all_fields*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	Prevents application against cross site scripting and HTML injection attacks
Recommended value	true
Default value	true
Security risk rating	8.8
Functional impact	This remediation enforces HTML-output encoding mechanism before the user data is rendered back to the user. If customer has any customization that involves rendering of the HTML attribute or content data, then there is a functionality impact.
Security risk	(High) User input should be securely treated when the data is being stored and processed on the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	application.This reduces client-side cross-site scripting attacks by output encoding the data.
Workaround	This property sanitizes all HTML fields in the system. If you must enable HTML sanitization on individual fields, see Enable sanitization on individual fields. You can also configure the inclusion list or exclusion list to sanitize HTML tags and attributes as per your organizations policy.
References	Enabling HTML sanitizer HTML sanitizer

To learn more about adding or creating a system property, see Add a system property.

Enable script sandbox [Updated in Security Center 1.3]

Use the *glide.script.use.sandbox* property to enable script sandboxing.

Prevent unauthorized or unauthenticated users from executing privileged script on your instance by enabling the script sandbox feature. The script sandbox is used to execute client-generated scripts, such as query conditions and GlideAjax expressions, in a "sandbox" environment that has restricted rights.

Without the script sandbox, unauthorized/unauthenticated users can execute privileged script on an instance. This can impact security across all areas, including, but not limited to potentially malicious access to all data on the instance.

Enable the script sandbox feature on your instance by setting the **glide.script.use.sandbox** system property to **true**.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

There are two cases in the ServiceNow AI Platform that enable the client to send scripts to the server for evaluation:

Filters or queries

It is legal to send a filter to the server such as `assigned_to=JavaScript:getMyGroups()`.

System API

API call enables the client to run arbitrary scripts on the server and receive a response.

If you enable the script sandbox, the script being evaluated at either of these two entry points runs in a sandbox with reduced rights, with the following characteristics:

- Only those business rules marked **Client callable** are available within the sandbox.
- Only script includes marked **Sandbox enabled** are available within the sandbox.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Certain API calls (largely, but not entirely, limited to ones dealing with direct DB access are not allowed.)
- You can't insert, update, or delete data from within the sandbox. For example, any calls to `current.update()`, are ignored. If you run the ServiceNow AI Platform without enabling script sandboxing, none of these restrictions apply.

Note: Beginning with the Xanadu release, script includes marked as **Glide AJAX enabled** (previously named **Client callable**) aren't accessible within the sandbox. Only those marked **Sandbox enabled** are available within the sandbox. When upgrading to the Brazil release from the Washington DC release or earlier, any script includes marked as **Client callable** are also marked as **Sandbox enabled**.

More information

Attribute	Description
Property name	*glide.script.use.sandbox*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	Enforces validation for the client-side JavaScript queries that are launched against the platform
Recommended value	true
Default value	true
Security risk rating	10
Functional impact	This remediation enforces validation for the client-side JavaScript queries that are launched against the ServiceNow AI Platform. There is a potential impact if customer has customizations that include hard-coded JavaScript queries to perform CRUD operations.
Security risk	(Critical) The ServiceNow AI Platform provides wide variety of features and functionality through JavaScript queries. However, without appropriate authorization and validation, there is a potential for an attacker to perform unauthorized operations against the platform.
References	*glide.script.use.sandbox* belongs to the same family of properties that secure and restrict execution of scripts originating from the client: • *glide.script.allow.ajaxevaluate*: See Disable AJAXEvaluate. • *glide.script.secure.ajaxgliderecord*: See Require AJAXGlideRecord ACL checking.

To learn more about adding or creating a system property, see Add a system property.

Enable KittyScript sandbox security enforcement

KittyScript sandbox enforcement prevents untrusted scripts from executing with unrestricted system privileges. The following properties control enforcement activation, level, and timing.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Configuring them incorrectly can cause malicious code to bypass security protections and access restricted APIs.

- `com.glide.script.sandbox.ks.watchdog.enabled` (default: `true`): Master control for the KittyScript sandbox security interpreter in ServiceNow Guarded Scripts framework. When set to `true`, all untrusted scope scripts are subject to sandbox enforcement. When set to `false`, disables KittyScript entirely.
- `com.glide.script.sandbox.ks.watchdog.auto.advance`: Controls whether the watchdog automatically advances from Phase 1 (detection-only) to Phase 3 (full rejection).
- `com.glide.script.sandbox.ks.watchdog.phase.duration.days`: Specifies how long each active phase persists before advancing to the next phase.
- `com.glide.script.sandbox.ks.watchdog.phase`: Sets the enforcement level (Phase 1–3) for authenticated script execution. Phase 3 enforces full restrictions.

Verify the following properties exist in the `sys_properties` table and set them to the specified values if they exist:

- `com.glide.script.sandbox.ks.watchdog.enabled` = `true`
- `com.glide.script.sandbox.ks.watchdog.auto.advance` = `true`
- `com.glide.script.sandbox.ks.watchdog.phase.duration.days` = `14`
- Create or update the `com.glide.script.sandbox.ks.watchdog.phase` property. Set the value to `3`.

More information

Attribute	Description
Configuration name	*com.glide.script.sandbox.ks.watchdog.enabled* *com.glide.script.sandbox.ks.watchdog.auto.advance* *com.glide.script.sandbox.ks.watchdog.phase.duratio* *com.glide.script.sandbox.ks.watchdog.phase*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean, Boolean, Integer, Integer
Recommended value	true, true, 14, 3
Default value	true, true, 14, 0
Fallback value	true, true, 14, 0
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 8 • CVSS rating: High • Security risk details: Disabling the *com.glide.script.sandbox.ks.watchdog.enabled*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	property removes all sandbox protections for untrusted scripts, allowing malicious or poorly-written code to execute with full system privileges and access restricted APIs. This can lead to data theft or system compromise. Disabling the *com.glide.script.sandbox.ks.watchdog.auto.advanc* property freezes enforcement at Phase 1 (detection-only), allowing scripts with unsupported features to continue executing indefinitely without sandbox restrictions, indefinitely deferring security hardening platform-wide. Setting the *com.glide.script.sandbox.ks.watchdog.phase.durat* property to a value too high delays enforcement phase transitions. This leaves the platform in permissive phases (1-2) longer than intended and extending the window where malicious scripts can bypass sandbox protections. Setting the *com.glide.script.sandbox.ks.watchdog.phase* property to permissive phases (1-2) allows untrusted scripts to execute without sandbox enforcement. This enables attackers to exploit vulnerable code paths, access unauthorized APIs, and potentially escalate privileges or exfiltrate data.
Functional impact	**When set with recommended values:** The system checks all scripts for security violations. Restrictions progressively enforce, blocking scripts from accessing unauthorized data or APIs. This is the secure, standard operating mode. **When turned off:** All script security checks are turned off. Scripts execute without restrictions, creating significant security risks. While disabling enforcement can temporarily resolve broken scripts during emergencies, it exposes the system to malicious or poorly written code.
Dependencies and prerequisites	None

Enforce KittyScript validation for guest sessions

The *com.glide.script.kittyscript.validation.mode* property controls JavaScript validation for unauthenticated (guest) users before it runs in the server-side sandbox.

- `block` or `block_guest`: Rejects scripts that use syntax or operations outside a minimal, restricted set.
- `warn` or `ignore`: Reduces or removes enforcement, allowing guest scripts to run under the platform's legacy sandbox restrictions only.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Set the *com.glide.script.kittyscript.validation.mode* property to `block` or `block_guest` in the `sys_properties` table. If it doesn't exist, create it and set it to `block`.

More information

Attribute	Description
Configuration name	*com.glide.script.kittyscript.validation.mode*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	block
Default value	block
Fallback value	block_guest
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 9.1 • CVSS rating: Critical • Security risk details: Allowing unauthenticated users to execute server-side JavaScript is a critical security risk. This code runs with server-side privileges and bypasses ordinary access controls. No valid credentials or user interaction is required to trigger it. An attacker who reaches this capability can use it to read, modify, or exfiltrate data, and to bypass the business logic and access restrictions that would otherwise apply.
Functional impact	This property controls how the server-side sandbox validates JavaScript in guest sessions. • `ignore`: Disables validation. Guest scripts execute without sandbox restrictions. • `warn`: Allows guest script execution. Scripts that violate sandbox restrictions are logged. • `block_guest` or `block`: Enforces sandbox restrictions. Scripts using unsupported syntax or disallowed operations are blocked. After enabling enforcement, test guest-facing functionality that uses dynamic script evaluation such as reference qualifiers and scripted default values to confirm it still works.
Dependencies and prerequisites	The *com.glide.script.sandbox.ks.watchdog.enabled* property must be set to `true`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Enable sanitization of inbound virtual agent chat messages

The *glide.cs.sanitize_inbound_messages.enabled* property controls whether Virtual Agent runs a dedicated HTML sanitization check on inbound chat messages sent from a requester to an agent.

When set to `true` (recommended), the platform strips unsafe HTML content from each inbound message. If content is removed, both the requester and the agent (in live-agent conversations) are notified that sanitization occurred. When set to `false`, inbound messages instead pass through only the legacy system-message sanitization path, and the dedicated inbound-content check is skipped.

To configure this property:

1. Navigate to `/sys_properties_list.do` on the instance.
2. Set the *glide.cs.sanitize_inbound_messages.enabled* property to `true`.

More information

Attribute	Description
Configuration name	*glide.cs.sanitize_inbound_messages.enabled*
Configuration type	System Properties (`/sys_properties_list.do`)
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	false
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 3.5 • CVSS rating: Low • Security risk details: If this property is not set to `true`, Virtual Agent chat messages from requesters skip this dedicated sanitization check. The message is delivered to the agent unfiltered. A requester can inject malicious HTML or script content into their message. When the agent views the message, the browser renders this content in the agent's session, creating a reflected cross-site scripting (XSS) attack against the agent.
Functional impact	Enabling this property adds an additional sanitization pass to every inbound Virtual Agent chat message. Messages containing certain markup are flagged, stripped, and replaced with a system warning to the requester and agent. Live-agent handoffs receive the same treatment rather than delivery as originally typed. Availability impact is minimal because the control affects message content and rendering only—not conversation flow or session continuity. **Test these scenarios:**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• >Inbound consumer and live-agent chat conversations • Messages containing HTML-like syntax or rich-control content (for example, topic-picker selections) Verify that legitimate messages are delivered without false warnings.
Dependencies and prerequisites	No effect unless *com.glide.cs.html.sanitizer.enabled* is set to `true`.

Enforce HTML sanitization

Use the *com.glide.security.check_unsanitized_html* property to enforce sanitization behavior of translated_html fields on a global level for field assignments.

The *com.glide.security.check_unsanitized_html* system property enforces sanitization behavior of translated_html fields on a global level for field assignments.

Ensure that the property *com.glide.security.check_unsanitized_html* is set to `enforce`.

⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*com.glide.security.check_unsanitized_html*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	enforce
Default value	enforce
Fallback value	log_only
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 7.3 • CVSS rating: High • Security risk details: An attacker could be able to execute arbitrary javascript in the victim's browser (XSS attacks).
Functional impact	None
Dependencies and prerequisites	None

Ensure Contextual Search Do Not Contain An Unvalidated Redirect [New in Security Center 7.0]

Prevent Contextual Search results from containing referral links outside the current domain with a system property.

The Contextual Search plugin displays search results in a new window using the *cxs_new_window* UI page. This UI page contains a referral link which can be set by providing a value to *sysparm_url*. When the *com.snc.contextual_search.cxs_new_window.force_relative_link* system property is set to **true**, *sysparm_url* can only contain links that are relative to the current domain. This restriction prevents the UI page from being used as an unvalidated redirect to an attacker-controlled website. When the property is set to **false**, *sysparm_url* can link to any website.

Set the *com.snc.contextual_search.cxs_new_window.force_relative_link* property to **true**. If the property doesn't exist on the System Properties [sys_properties] table, the default value is **false**. If the property exists on the table, it defaults to **true**.

More information

Attribute	Description
Configuration name	*com.snc.contextual_search.cxs_new_window.force_rel*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 3.1 • CVSS score: Medium • When set to **false**, *sysparm_url* can link to any website, which allows the UI page to be used as an unvalidated redirect to an attacker-controlled website.
Functional impact	When set to **true**, *sysparm_url* is only allowed to contain links that are relative to the current domain. This restriction means that the UI page can only ever link to web pages on the current domain. However, the UI page is meant to display search results from the current domain and should only ever link to the current domain.
Dependencies and prerequisites	The Contextual Search (com.snc.contextual_search) plugin must be active.

To learn more about adding or creating a system property, see Add a system property.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Disable AJAXEvaluate

Use the *glide.script.allow.ajaxevaluate* to protect the system API from vulnerabilities of Client script execution through AJAX calls.

The AjaxEvaluator processor executes these scripts in sandbox however there are several additional properties which can allow the scope of activities in the sandbox to expand or be turned off entirely. In a worst case scenario a user can easily execute scripts as an admin privilege.

Ensure that the *glide.script.allow.ajaxevaluate* system property is set to **false**.

Elevation to the security_admin role is required to edit the property.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.script.allow.ajaxevaluate*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 7.3 • CVSS rating: High • Security risk details: If this property is not set to **false**, then the system API can be vulnerable to client script execution through AJAX calls.
Functional impact	None
Dependencies and prerequisites	None

Disable Entity Expansion within the XMLDocument2 Streaming Parser

If customizations do not require entity expansion, use the *glide.stax.allow_entity_resolution* property to completely disable external entity expansion. The XML completes parsing but doesn't include any internal or external entities.

If the *glide.stax.allow_entity_resolution* is not set to the recommended value of **false**, then this property allow XML entities to be expanded during parsing by the streaming parser (XMLDocument2).

Ensure that the property *glide.stax.allow_entity_resolution* exists in the System Properties [sys_properties] table and is set to **false**. If the property does not appear in the System Properties [sys_properties] table the default value is **true**.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	true
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 9.0 • CVSS rating: Critical • Security risk details: XML entity expansion can lead to attacks such as ability to read system files, and Denial of Service.
Functional impact	None
Dependencies and prerequisites	Before setting this property: • Set the *glide.xml.entity.whitelist.enabled* and *glide.stax.whitelist_enabled* properties to true. To learn more, see Restrict XML external entities and Require XMLdoc2 entity validation with allowlist. • Define a listing of comma-delimited FQDN in the *glide.xml.entity.whitelist* property, which is the only URLs that can be reached using XML Entity processing. property. To learn more, see Restrict XML external entities.

Disable external content URL

Manage how external link metadata is used in your instance with Connect Chat.

If the *glide.ui.url.external.content* system property isn't set to the recommended value of **false**, then Connect chat retrieves external link metadata in order to render richer content in messages with links to Youtube, news articles, images, etc.

Ensure that the Glide Property *glide.ui.url.external.content* exists in the System Properties [sys_properties] table and is set to the value **false**. If the property does not appear in the table, add a new record.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.ui.url.external.content*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	false
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 7.2 • CVSS score: High • Security risk details: This could lead to Server Side Request Forgery (SSRF) attacks.
Dependencies and prerequisites	None
References	Connect Chat

Disable JavaScript tags in embedded HTML

Use the *glide.ui.security.codetag.allow_script* property to disable support for embedding HTML JavaScript code created using of the [code] tag.

If *glide.ui.security.codetag.allow_script* is not set to the recommended value of **false**, then this property allows rendered HTML in journal fields and forms which opens room for XSS attacks. Malicious HTML needs to be put between code tags for example [code][/code].

Ensure that the *glide.ui.security.codetag.allow_script* property exists in the System Properties [sys_properties] table and is set to **false**.

⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.ui.security.codetag.allow_script*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	true
Category	Validation, sanitization, and encoding

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: High • CVSS rating:8.8 • Security risk details: Uncontrolled JavaScript risks Cross-Site Scripting (XSS) attacks, enabling malicious actors to inject and execute harmful scripts in the user's browser. Such attacks can lead to session hijacking, credential theft, and compromise of sensitive data.
Functional impact	None
Dependencies and prerequisites	None

Restrict downloadable MIME types

The *glide.ui.attachment.download_mime_types* property will force the specified list of dangerous file types to be downloaded to the client and not viewed inline in the browser.

If the **glide.ui.attachment.force_download_all_mime_types** system property is set to **true**, then the *glide.ui.attachment.download_mime_types* property is overridden so that all MIME types will be downloaded rather than rendered by the browser. For example, downloading text/html forces an HTML file to be downloaded to the client as a file rather than viewed inline in the browser, preventing a XSS attack.

Ensure that the property *glide.ui.attachment.force_download_all_mime_types* is set to **true**. If the property does not exist in the System Properties [sys_properties] table, the default value is **false**.

Note: The security_admin role is required to edit the property.

More information

Attribute	Description
Configuration name	*glide.ui.attachment.download_mime_types*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 6.4 • CVSS rating: Medium • Security risk details: XSS can lead to easily attained privilege escalation to higher roles such as admin where more lateral movement can be taken.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	This remediation enforces performance of validation checks before performing an action when you click an attachment in a application. There is no potential impact, but the user experience is altered.
Dependencies and prerequisites	None

Enable HTML sanitizer within Virtual Agent

Use the *com.glide.cs.html.sanitizer.enabled* property to enable HTML sanitizer service.

The *com.glide.cs.html.sanitizer.enabled* system property controls the whether the HtmlSanitizerService is enabled. If *com.glide.cs.html.sanitizer.enabled* is not set to **true**, then a Stored Cross-Site Scripting (XSS) attack is possible in the VA web client.

Ensure that the property *com.glide.cs.html.sanitizer.enabled* is set to **true**.

⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*com.glide.cs.html.sanitizer.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 8.0 • CVSS rating: High • Security risk details: An XSS vulnerability can facilitate privilege escalation to higher-level roles, such as administrator, enabling broader lateral movement within the system.
Functional impact	This remediation enforces HTML-output encoding mechanism before the user data is rendered back to the user. If customer has any customization that involves rendering of the HTML attribute or content data, then there is a functionality impact.
Dependencies and prerequisites	None

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Enable Jelly JS interpolation protection

Use the *glide.ui.jelly.js_interpolation.protect* property to ensure that any JavaScript about to be executed on a Jelly page is protected from injection with the help of Jelly interpolation.

The *glide.ui.jelly.js_interpolation.protect* system property allows you to turn on or off interpolation protection. Interpolation protection ensures that when Jelly expressions are used in JavaScript, they must be deemed safe by either falling under certain categories OR being marked as SAFE in the expression itself. Without this mitigation enabled, a malicious actor can send a crafted GET parameter to a Jelly page and cause the contents of that parameter to be evaluated as server-side JavaScript with admin privileges.

Ensure that the property *glide.ui.jelly.js_interpolation.protect* is set to **true**.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.ui.jelly.js_interpolation.protect*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true in Australia and newer, false prior
Fallback value	true in Australia and newer, false prior
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 9.0 • CVSS rating: Critical • Security risk details: Dangerous jelly expressions interpolated in JavaScript are allowed and user can execute code using jelly template.
Functional impact	Enabling this property causes the platform to reject Jelly JavaScript expressions that aren't explicitly recognized as safe or marked as SAFE. Instance owners should test custom UI pages, macros, and portal widgets that use Jelly-interpolated JavaScript expressions after making this change. Confirm that legitimate expressions continue to render as expected. Custom Jelly content that relies on dynamic, unmarked expressions require updates to use the SAFE designation to continue functioning.
Dependencies and prerequisites	None

Enable Jelly JS interpolation protection for nested expressions

Manage the interpolation protection on your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Use the *glide.ui.jelly.js_interpolation.protect_nested_expressions* system property to turn on or off interpolation protection specifically for nested Jelly expressions. Interpolation protection ensures that when Jelly expressions are used in JavaScript, they must be deemed safe by either falling under certain categories OR being marked as SAFE in the expression itself. This property was added to protect against possibly dangerous Jelly expressions which are nested in another Jelly expression.

Ensure that the *glide.ui.jelly.js_interpolation.protect_nested_expressions* system property exists and is set to the value **true**. If the property does not appear in the System Properties [sys_properties] table, add a new record.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.ui.jelly.js_interpolation.protect_nested_exp*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 9 • CVSS score: Critical • Security risk details: Unprotected interpolated jelly expression may result in a malicious actor sending a crafted GET parameter to a Jelly page and cause the contents of that parameter to be evaluated as server-side JavaScript with admin privileges.
Functional impact	None
Dependencies and prerequisites	None

Enforce relative links

Use the *glide.cms.catalog_uri_relative* property to enforce relative links from the URI parameter on `/ess/catalog.do`.

The *glide.cms.catalog_uri_relative* system property enforces relative links from the URI parameter on /ess/catalog.do. If *glide.cms.catalog_uri_relative* is not set to the recommended value of **true**, then the URL isn't sanitized with the enforceRelativeURL(url) function.

Note: This property impacts the legacy Content Management System (CMS) which has been replaced with Service Portal.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Ensure that the property *glide.cms.catalog_uri_relative* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.cms.catalog_uri_relative*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 2.6 • CVSS rating: Low • Security risk details: Absolute URLs can pose a security risk when used as a part of parameter or a field value, thus redirecting the source page to an adversary-controlled website.
Functional impact	This remediation enforces validation on the catalog page such that only relative URLs are permitted. Existing links to external web applications will be broken.
Dependencies and prerequisites	None

Enforce URL allowlist check

Use the *glide.security.url.whitelist* system property to add extra layer of validation to ensure whether any external URL introduced should be a part of inclusion listed URLs.

If the **glide.security.url.whitelist.strict_check** system property isn't set to the recommended value of **true** then all external URLs are allowed for redirection when *glide.security.url.whitelist* is empty. If *glide.security.url.whitelist* is not empty, then only external URLs in the list are allowed. Either setting *glide.security.url.whitelist.strict_check* to **true** or ensuring *glide.security.url.whitelist* is set to a non-empty value with the allowed external URLs leaves the instance in a secure state.

Ensure that the property **glide.security.url.whitelist.strict_check** is set to **true** or the property **glide.security.url.whitelist.strict_check** is set to a value.

More information

Attribute	Description
Configuration name	• **glide.security.url.whitelist.strict_check** • *glide.security.url.whitelist*

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Configuration type	System Properties (/sys_properties_list.do)
Data type	• Boolean • String
Recommended value	• true • Comma-separated of permitted URLs
Default value	true,""
Fallback value	• true • <empty>
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 6.3 • CVSS rating: Medium • Security risk details: If all external URLs are allowed for redirection, this could allow an attacker to redirect a user to a malicious website.
Functional impact	This remediation enforces validation on logout page. It might have a functional impact on a user of an instance with an SSO/SAML configuration.
Dependencies and prerequisites	None

Escape Excel formulas

Use the *glide.export.escape_formulas* property to prevent Excel Injection, also, known as formula injection.

Prevent potentially malicious formulas in programs such as Excel from being executed after exporting and opening the file by escaping formulas in these files. Excel injection occurs when websites embed untrusted entries inside Excel files. When you use a spreadsheet application such as Microsoft Excel, or LibreOffice Call, to open a file, any cells starting with +, -, =, or @ are interpreted as a formula unless properly escaped. Malicious formulas pose a risk even when the spreadsheet doesn't contain any sensitive information, as they can be used to compromise the viewer's computer through code execution.

Set the **glide.export.escape_formulas** system property to **true** to escape these formulas from executing.

More information

Attribute	Description
Property name	*glide.export.escape_formulas*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Validation, sanitization, and encoding
Purpose	To prevent application against the Excel or formula injection.
Recommended value	true
Default value	true
Security risk rating	6.4
Functional impact	Maliciously crafted formulas can be used for hijacking the user's computer by exploiting vulnerabilities in the spreadsheet software.
Security risk	(Moderate) Malicious formulae pose a risk even when the embedding spreadsheet doesn't contain any sensitive information, as they can be used to compromise the viewer's computer.
Workaround	As an alternative consider stripping all trailing white spaces where possible, and limiting all client-supplied data to alpha-numeric characters.
References	Available system properties

To learn more about adding or creating a system property, see Add a system property.

Escape HTML in list views [Updated in Security Center 1.3 and 1.5]

Use the *glide.ui.escape_html_list_field* property to force HTML escapes for HTML fields in a list view.

Set *glide.ui.escape_html_list_field* to **true** to prevent HTML from being rendered in HTML fields in list view. Leaving HTML sanitization inactive platform wide (via system property) or by field (via a schema attribute), may lead to XSS style attacks. XSS attacks may allow a low privileged user to hijack the session of a high privileged user or interfere in standard web application behaviors, including redirects or defacement.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It's non-revertible.

More information

Attribute	Description
Property name	*glide.ui.escape_html_list_field*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	To help prevent application against cross-site scripting attacks
Recommended value	true
Default value	true
Security risk rating	3.1

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	This remediation enforces HTML encoding to occur on the UI at the HTML parser level and thus renders back encoded results to the user. It can have a functionality impact based on the instance user interaction with the resulted data.
Security risk	(High) Input validation must occur on the application to defend against cross-site scripting attacks. These attacks enable foreign scripts to execute on user sessions in the logged in browser's context. Attackers can use it to steal session information and sensitive data.
References	High Security Settings

To learn more about adding or creating a system property, see Add a system property.

Escape JavaScript [Updated in Security Center 1.3]

Use the *glide.html.escape_script* property to force escape from JavaScript (`<script></script>`) tags in HTML fields during list views.

The glide property *glide.html.escape_script* helps sanitize HTML fields. If *glide.html.escape_script* is not set to the recommended value of true, then inputs will not be sanitized for HTML fields (output encoding) from a backend Java context by removing embedded JavaScript. Javascript in HTML fields can lead to stored and reflected XSS. The ability to have XSS can lead to easily attained privilege escalation to higher roles such as admin where more lateral movement can be taken.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.html.escape_script*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	To prevent cross-site scripting attacks against an application.
Recommended value	true
Default value	true
Security risk rating	8.8
Functional impact	This remediation enforces JavaScript escaping to occur on the UI and renders encoded results to the user. It can have an impact on functionality, based on the instance user interaction with the resulting data
Security risk	(High) Input validation must occur in the application to defend against cross-site scripting attacks. These

Attribute	Description
	attacks enable foreign scripts to execute on user session in the logged in browser's context. Attackers can use it to steal session information and sensitive data.
References	Available system properties High Security Settings

To learn more about adding or creating a system property, see Add a system property.

Escape jelly script

Use the *glide.ui.escape_all_script* property to force escape of all scripts injected into Jelly.

This property escapes all the JS and HTML strings included in <j:jelly> ... </j:jelly> before they are written to the output stream, preventing several XSS issues from occurring. If *glide.ui.escape_all_script* is not set to the recommended value of true, then escaping of scripts injected into Jelly is disabled. Without this mitigation, the platform becomes widely open to a variety of script injection attacks. An attacker could execute arbitrary Rhino scripts on the instance.

Warning: Be careful when using these tags. If user input is displayed here it can open a security vulnerability.

More information

Attribute	Description
Property name	*glide.ui.escape_all_script*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Category	Validation, sanitization, and encoding
Purpose	If the property is not set to **true**, developers have to perform several steps on each custom Jelly script to prevent XSS issues. These steps include locating the Jelly variables being sent to output stream to render on web pages, and performing escaping on each of the following tags: `$â {JS:expression}` `$â {HTML:expression}` OR `$â {JS,HTML:expression}`
Recommended value	true
Default value	true
Security risk rating	7.3

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	This remediation enforces Jelly escaping at the parser level. It can have a functionality impact on user interaction with the resulting data.
Security risk	(High) Input validation has to occur on all the user input being entered on the application. By doing so, injection attacks against the platform can be defended and protected.
Workaround	The UI may be affected because some of the scripts and HTML tags designed for rendering on a web page may appear broken. This remediation sends the output encoded page to the browser to render. For example, instead of `'my string here'`, it might display `'<u>my string here</u>` as the `<u>` tag was properly escaped. In this case, to prevent escaping, add the NOESC prefix to Jelly expression to prevent JS escaping. For example: • Before: ($[jvar_context_menus]); • After: `($[NOESC:jvar_context_menus]);` • Before: $[jvar_ui_policy_scripts] • After: `$[NOESC:jvar_ui_policy_scripts]` ⚠ **Warning:** Be careful when using these tags. If user input is displayed here it can open a security vulnerability.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Recommended value	true
Default value	true
Fallback value	true
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 6.5 • CVSS score: Medium • Security risk details: It is possible to execute malicious script like a cross-site scripting vulnerability.
Dependencies and prerequisites	None
References	Workflow administration

Escape XML markup

Use the *glide.ui.escape_text* property to force escape of XML values at the parser level before transmitting them to the client's browser.

Use the *glide.ui.escape_text* system property to escape XML values at the parser level for the user interface. It prevents reflected and stored cross-site scripting attacks. This property is not applicable in Service Portal.

Cross-site scripting occurs when an attacker injects malicious JavaScript into an entry point. The platform/application fails to escape the malicious JavaScript before transmitting it to the victim's browser for execution. Escaping in this context means the following:

- **&** --> `&`
- **<** --> `<`
- **>** --> `>`
- **"** --> `"`
- **'** --> `'`
- **/** --> `/`

Example: `<script>alert('XSS Attack');</script>`

Escaping: `<script>alert('XSS Attack');</script>`

Ensure the *glide.ui.escape_text* property exists in the System Properties [sys_properties] table and is set to **true**.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.ui.escape_text*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 8.8 • CVSS rating: High • Security risk details: If *glide.ui.escape_text* is not set to the recommended value of **true**, then XML values will not be escaped at the parser level for the user interface; this will leave jelly templates susceptible to reflected and stored cross site scripting attacks.
Functional impact	None
Dependencies and prerequisites	None

Escape xml response

Manage how XML escapes are handled on your instance.

Use this property to manage if XML responses are escaped. If the property is set to the recommended value of **false**, then XML responses will not be escaped which can lead to XML injection attack. The injection of unintended XML content into an XML message can alter the intended logic of an application.

More information

Attribute	Description
Configuration name	*glide.soaprequest.unescape_xml_response*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 6.4 • CVSS score: Medium • Security risk details: Setting this property to **false** disables XML escaping, which could lead to XML injection attack.
Dependencies and prerequisites	None

Restrict access to GlideSystemUserSession scriptable API

The client callable GlideSystemUserSessionSandbox scriptable API exposes GlideSystemUserSession's addErrorMessageNoSanitization and addInfoMessageNoSanitization methods to the JavaScript sandbox. This allows all users to call this method via script.

The methods `gs.addErrorMessageNoSanitizationMessaging()` and `gs.addInfoMessageNoSanitization()` are used within the scripting environment for logging and notifications. Both of these are available in the sandbox if this property is not set to the recommended value of **false**. The sandbox is a low privileged scripting environment available to unauthenticated and no role users. Both of these methods can be used to display unsanitized input to a user.

Ensure that the `glide.sandbox.usersession.allow_unsanitized_messages` system property is set to **false**. If this property does not exist on the System Properties [sys_properties] table, create the property.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	`glide.sandbox.usersession.allow_unsanitized_messag`
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	true
Category	Access control
Security risk	• Severity score: 8.1 • CVSS rating: High • Security risk details: Displaying unsanitized input to the user is dangerous, as unsanitized input may contain dangerous code that runs in the user's browser. This can be utilized for traditional reflected XSS attacks. Reflected XSS attacks can be used in multiple scenarios, including session hijacking.
Functional impact	None
Dependencies and prerequisites	None

Restrict allowed Java packages [Updated in Security Center 1.3]

Configuring these properties protect from dangerous APIs being exposed to the scripting engine.

Configure the system tables and install the recommended plugin accordingly.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

If the *sys_whitelist_member* and *sys_whitelist_package* table are not empty values, then dangerous APIs may be exposed to the scripting engine. Entries correspond to the Java namespace that have not been approved by ServiceNow security teams.

Install the Packages call removal tool. See Packages call removal tool for details.

Contact Customer Service and Support to edit these tables.

More information

Attribute	Description
Table, plugin name	Tables: • *sys_whitelist_member* • *sys_whitelist_package* Plugin: com.glide.script.packages_call_removal
Configuration type	Tabular Configuration, Plugins
Category	Validation, sanitization, and encoding
Purpose	Protect from dangerous APIs being exposed to the scripting engine.
Recommended value	Empty
Default value	None. This is a table configuration and not a Glide Property, so there is no default value.
Configuration type	table list, plugin
Security risk	(High) Dangerous APIs may be exposed to the scripting engine. These supported APIs will likely introduce instability and insecurity within the instance.
Security risk rating	8.2

To learn more about adding or creating a system property, see Add a system property.

Packages call removal tool

Activate and run the Packages Call Removal Tool (*com.glide.script.packages_call_removal*) plugin, and then consider whether each of the proposed changes should be completed or rejected.

The Packages Call Removal Tool is a plugin that:

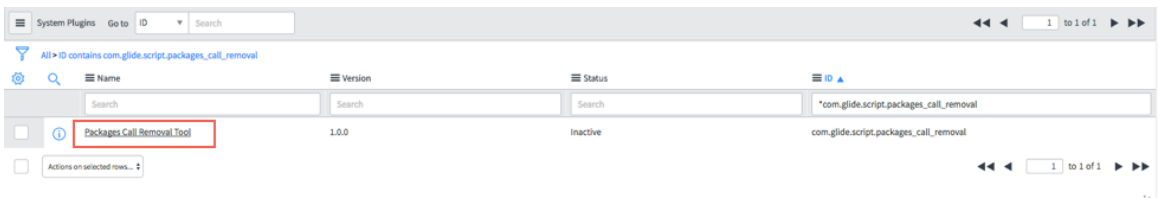
- Scans scripts for package calls to ServiceNow AI Platform Java classes.
- Proposes changes to replace them with preferred GlideScriptable names.
- Facilitates the script changes.

Note: If this record is a base system record, using the recommendation from the tool causes the item to be marked as customer_update. However, it may still be useful to use this tool because it flags Packages,xxx calls.

The Packages Call Removal Tool might report some package calls used in `sa_mapping_ext_commands` and `sa_custom_operation`. These package calls belong to the MID Server. As there are no classes, the code runs in MID Server. If you find any of the

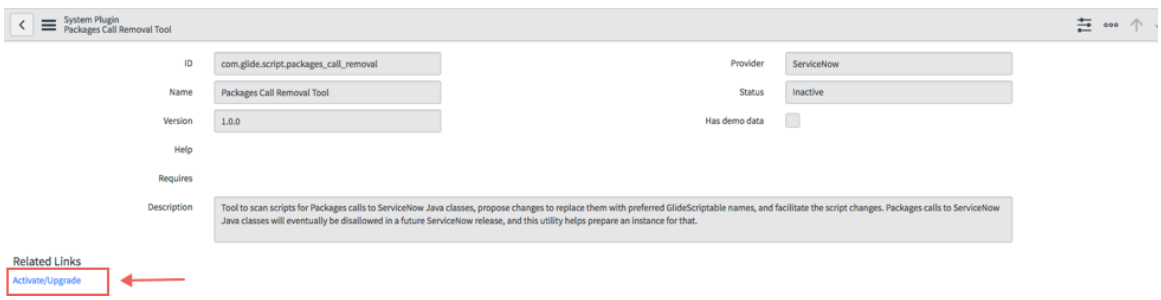
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

following listed package calls in the Errors section, mark them as Rejected (Ignored). The tool doesn't report that package call again.



- `Packages.com.snc.sw.util.JSONUtil.toJSONPlain(file_content);`
- `Packages.com.snc.sw.util.JSONUtil.toJSONPlain(file_name);`
- `Packages.com.snc.sw.commands.HttpCallHandler;`
- `Packages.com.snc.sw.dto.ProviderType.SSH`

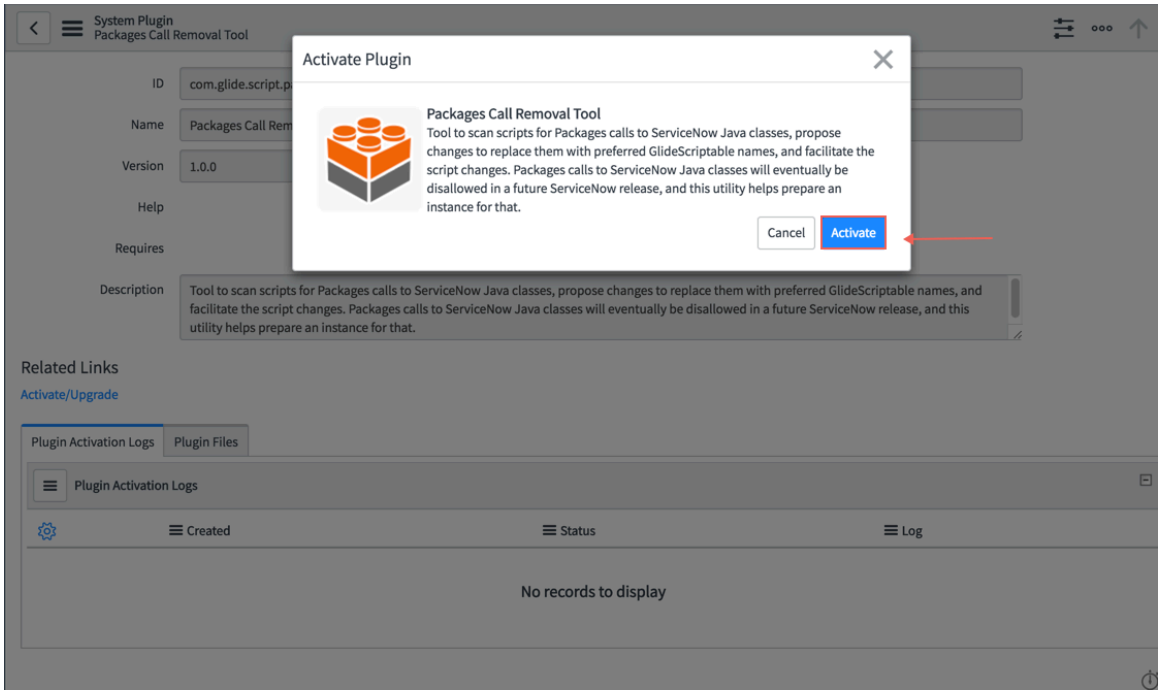
More information



Attribute	Description
Plugin Name	com.glide.script.packages_call_removal
Configuration type	System Definition > Plugins
Purpose	To remove/replace unauthorized package/member calls with Glide Acceptable (GlideScriptable) names that only allow authorized access to data.
Recommended value	Active
Functional impact	This remediation would replace the package calls with *`GlideScriptable`* APIs, and can affect the customizations that include package calls. The tool doesn't actually replace package calls automatically. Instead, it provides suggestions that are stored into the packages_call_item table. Your administrator can then decide whether to accept or reject the proposed change.
Security risk	(Medium) Client-side API calls that result in data retrieval or object access on server are deemed to be dangerous from a security standpoint. They should be validated for authorization and restriction for sensitive object access.

Steps to configure

1. Navigate to **System Definition** > **Plugins**



2. Search for the plugin ID = *`com.glide.script.packages_call_removal`*.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. Click **Activate/Upgrade** to activate the plugin.

4. To check inclusion list package calls and inclusion list member calls, complete the actions outlined in the Steps to Configure sections in Restrict allowed Java packages [Updated in Security Center 1.3].

Unset LDAP Initial distinguished name [Updated in Security Center 1.3 and removed in 2.0]

Use this property to manage the distinguished name of a LDAP Server record.

This property controls the distinguished name of a LDAP Server record which is inserted when running an out-of-the-box (OOB) fix script. If it is set to the recommended value of "" or blank, then LDAP server data can be enumerated by a lower privilege user.

More information

Attribute	Description
Configuration name	*glide.ldap.initial.dn*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	blank
Default value	blank
Category	Validation, sanitization, and encoding

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 2.7 • CVSS score: Low • Security risk details: Setting the property value to "" or blank could make LDAP server data accessible to a lower privilege user.
Dependencies and prerequisites	None

Enforce strict security of session cookies

Use the *glide.ui.secure_cookies* property to require properly formatted cookies

If *glide.ui.secure_cookies* isn't set to the recommended value of **true**, then additional cookie security and strict cookie validation isn't performed.

Ensure that the property *glide.ui.secure_cookies* is set to **true**.

⚠ **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.ui.secure_cookies*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 7.1 • CVSS rating: High • Security risk details: This could allow an attacker to bypass cookie validation leading to unauthorized resource access.
Functional impact	When the property is set to true, improperly formatted cookies are rejected. When such a cookie is rejected, the user must login again.
Dependencies and prerequisites	None

Minimize entity expansion threshold for GlideXMLUtil scriptable

Use the *glide.xmlutil.max_entity_expansion* property to change the maximum entity expansion limit to a smaller number.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The *glide.xmlutil.max_entity_expansion* system property controls the maximum amount of entity expansion within an XML parser. If *glide.xmlutil.max_entity_expansion* isn't set to the recommended value of 3000 or less, then the GlideXMLUtil parsing scriptable may be vulnerable to denial of service attacks.

Ensure that the property *glide.xmlutil.max_entity_expansion* is set to 3000 or less.

If the instance is on Washington or later, the default implied value is 3000 if the System Properties [sys_properties] record does not exist. If the instance is not on Washington or later, the recommendation is for the instance admin to create a System Properties [sys_properties] and set the value to 3000.

Note: 500 is the default minimum imposed by the ServiceNow AI Platform, which is considered to be a safe threshold.

More information

Attribute	Description
Configuration name	
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	Less than or equal to 3000
Default value	3000
Fallback value	3000
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 5.3 • CVSS rating: Medium • Security risk details: A Denial-of-Service (DoS) vulnerability poses a security risk by allowing attackers to overwhelm or crash a system, rendering it unavailable to legitimate users and potentially disrupting critical operations.
Functional impact	If the customization is using large entity expansion, then, the ServiceNow AI Platform might block further processing.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Prevent empty ACL creation

Set the *glide.security.empty_acl.popup_window.enabled* property to the secure value of true to block attempts to create, update, or save an invalid ACL. This setting will also provide a client-side model to configure a role or security attribute for the ACL.

The *glide.security.empty_acl.popup_window.enabled* property controls whether users making form-based edits to ACL [sys_security_acl] records can create, update, or save an

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

invalid ACL that has an invalid data condition, script, security attribute, or roles list, or otherwise does not have any configured (an "empty ACL"). As of the Xanadu release, an empty ACL will completely deny access. On versions prior to Xanadu, empty an ACL will allow unconditional access.

When the *glide.security.empty_acl.popup_window.enabled* property is set to a secure value of **true**, attempts to create, update, or save an invalid or empty ACL will be blocked, and a client-side model will be provided to configure a role or security attribute for the ACL. If the property is insecurely set to any other value, then such attempts will be allowed and no client-side model will be displayed.

Important: This property is case sensitive. A value of "True" (capital "T") will be equivalent to **false**. Additionally, this property will only function when the High Security (com.glide.high_security) plugin is installed and active.

Ensure the that the *glide.security.empty_acl.popup_window.enabled* property is set to **true** and confirm that the High Security (com.glide.high_security) plugin is active.

More information

Attribute	Description
Configuration name	*glide.security.empty_acl.popup_window.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	true
Default value	true
Fallback value	
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 6.5 • CVSS score: Medium • Security risk details: Misconfigured or empty Access Control Lists (ACLs) can unintentionally grant unrestricted access to sensitive data and system functionality. When ACLs lack proper conditions, roles, or security attributes, they fail to enforce authorization boundaries, enabling attackers or unauthorized users to bypass security controls. This can lead to data breaches, privilege escalation, and compromise of confidentiality, integrity, and availability across the platform.
Dependencies and prerequisites	None
Functional impact	This property allows the user to toggle the empty ACL warning pop-up on and off.
References	Prevent empty ACL creation

Prevent Reuse of REST API Sessions in UI/Web

Prevent REST API session cookies from bypassing Single Sign-On (SSO) and Multi-Factor Authentication (MFA) controls using a system property.

Use the *com.glide.processors.aprocessor.donot_reuse_api_session* to help prevent the cookies associated with the session created through the REST API from being reused to initiate UI/web sessions.

Verify that *com.glide.processors.aprocessor.donot_reuse_api_session* exists in the System Properties [sys_properties] table and is set to `true`.

More information

Attribute	Description
Configuration name	*com.glide.processors.aprocessor.donot_reuse_api_se*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Session management
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: Reusing REST API session cookies for a web session bypasses Single Sign-On (SSO) and Multi-Factor Authentication (MFA) controls. This bypass can be an escalation of intended privileges. SSO and MFA controls are important requirements to help prevent unauthorized access to data.
Functional impact	When *com.glide.processors.aprocessor.donot_reuse_api_se* is set to true: • API session cookies can no longer be reused to initiate web sessions. • All web sessions require full authentication (SSO/MFA), regardless of any existing API session. Potential Breakage:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Custom integrations, scripts, or legacy workflows that relied on the ability to transition from an API session to a web session without re-authentication will fail. • Automated processes or tools that previously bypassed SSO/MFA using API session cookies are forced to complete the full authentication flow. • Users may experience unexpected authentication prompts if their workflows were implicitly relying on this behavior. Before enabling, customers should review integrations and customizations: • Audit all integrations, scripts, and tools that interact with the instance via API and web interfaces. • Identify any that may be relying on session cookie reuse for seamless transitions between API and web sessions.
Dependencies and prerequisites	None

Define restricted downloadable MIME types

Use the *glide.ui.attachment.force_download_all_mime_types* property to download MIME types and not to render inline in the browser.

If the *glide.ui.attachment.download_mime_types* property doesn't include dangerous MIME types such as text/html, image/svg, image/svg+xml, application/xml, and application/xhtml+xml, then those dangerous files could be rendered inline in the browser, which could lead to Cross-Site Scripting (XSS) attacks.

This property is a comma-separated list of attachment MIME types that are downloaded to the client and don't render inline in the browser. For example, including text/html forces HTML files to be downloaded to the client as attachments rather than viewed inline in the browser. Maintaining this list properly by including all dangerous MIME types prevents Cross-Site Scripting attacks.

Note: This property's protection is only relevant when the *glide.ui.attachment.force_download_all_mime_types* property is set to **false**.

If the *glide.ui.attachment.force_download_all_mime_types* is set to **false**, verify that the *glide.ui.attachment.download_mime_types* system property includes the dangerous MIME types `text/html,image/svg,image/svg+xml,application/xml`.

More information

Attribute	Description
Configuration name	*glide.ui.attachment.force_download_all_mime_types*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	String (Comma-separated list of MIME types)
Recommended value	text/html,image/svg,image/svg+xml,application/xml,application/xhtml+xml
Default value	text/html,image/svg,image/svg+xml,application/xml,application/xhtml+xml
Fallback value	''
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 6.3 • CVSS score: Medium • Security Risk: Maintaining this list properly can prevent cross site scripting attacks.
Dependencies and prerequisites	This check is only relevant when the *glide.ui.attachment.force_download_all_mime_types* is set to **false** or doesn't exist in the System Properties [sys_properties] table.

Restrict uploaded MIME types

Use the *glide.security.file.mime_type.validation* property to activate MIME type checking for uploads. You can enable (set the property to **true**) or disable (set it to **false**) MIME type validation for file attachments.

The *glide.security.file.mime_type.validation* system property is used to activate MIME type checking for uploads.

Ensure that the property *glide.security.file.mime_type.validation* exists in the System Properties [sys_properties] and is set to **true**. If the property does not appear in the System Properties [sys_properties] table, add a new record.

More information

Attribute	Description
Configuration name	*glide.security.file.mime_type.validation*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Validation, sanitization, and encoding

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 5.4 • CVSS rating: Medium • Security risk details: MIME type validation for file attachments will not take place which could allow malicious file types to be uploaded.
Functional impact	This remediation enables MIME type verification on the attachments to the application. No functionality impact, unless there is a malicious intent in uploading the files as this validation is merely checking for mis-sync between the MIME type and the data.
Dependencies and prerequisites	None

Restrict XML external entities

Configure system properties to ensure that your instance only processes XML from trusted sources to help prevent XML external entity (XXE) attacks.

Use the *glide.xml.entity.whitelist* and *glide.xml.entity.whitelist* system properties to prevent your instance from processing XML from untrusted sources.

XML external entity (XXE) attacks occur when a malicious actor modifies incoming XML (such as adding HTTP requests) to access data or intact with otherwise restricted systems. To help prevent these attacks, the *glide.xml.entity.whitelist.enabled* system property limits the sources from which your instance executes XML. Use the *glide.xml.entity.whitelist* property to define a set of trusted sources.

Ensure that the *glide.xml.entity.whitelist* system property exists in the System Properties [sys_properties] table, and is set to `http://java.sun.com/j2ee/dtds/`. Ensure that the *glide.xml.entity.whitelist.enabled* system property exists in the System Properties [sys_properties] table and is set to the value `true`.

Tip:

Values other than `http://java.sun.com/j2ee/dtds/` can be included in the *glide.xml.entity.whitelist* property, but are unnecessary for the out of the box platform state. Review any additional values to determine if they are safe.

More information

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

Attribute	Description
Configuration name	• *glide.xml.entity.whitelist* • *glide.xml.entity.whitelist.enabled*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	• Comma-separated list • Boolean String
Recommended value	• http://java.sun.com/j2ee/dtds/ • true
Default value	• http://java.sun.com/j2ee/dtds/ • true
Fallback value	• http://java.sun.com/j2ee/dtds/ • true
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 9.8 • CVSS score: Critical • Security risk details: An XML Eternal Entity (XEE) attack can allow attackers to access data or perform unauthorized actions via crafted XML payloads.
Functional impact	If the customization is using external entity, not inclusion listed in the *glide.xml.entity.whitelist* property, the NOW Platform might block further processing.
Dependencies and prerequisites	None

Require XMLdoc2 entity validation with allowlist

If customizations do not require entity expansion, use the *glide.xmlutil.max_entity_expansion* property to completely disable external entity expansion. The XML completes parsing but doesn't include any internal or external entities.

If the glide property *glide.stax.whitelist_enabled* doesn't exist in the System Properties [sys_properties] table, or is not set to the recommended value of **true**, then all external entities are allowed when the glide property *glide.stax.allow_entity_resolution* is set to the value of **true**.

If customizations don't require entity expansion, use the *glide.stax.allow_entity_resolution* property to completely disable external entity expansion. The XML completes parsing but doesn't include any internal or external entities.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- If you set *glide.stax.allow_entity_resolution* to **true**, all external entities attempt to resolve or expand subject entities, subject to the setting of the *glide.stax.whitelist_enabled* property.
- If you set *glide.stax.allow_entity_resolution* to **false**, all entity resolution and expansion is blocked. To learn more about this property, see Disable Entity Expansion within the XMLDocument2 Streaming Parser.

When **glide.stax.whitelist_enabled** is set to **true**, define a listing of comma-delimited FQDN in the **glide.xml.entity.whitelist** property, which are the only URLs that can be reached using the XML entity processing property. To learn more, see Restrict XML external entities. Attackers can use this vulnerability to expand data exponentially in an External Entities Expansion (XXE) attack, quickly consuming all system resources.

Prerequisites

Before setting this property:

- Set the *glide.xml.entity.whitelist.enabled* and *glide.stax.whitelist_enabled* properties to **true**. To learn more, see Restrict XML external entities.
- Define a listing of comma-delimited FQDN in the *glide.xml.entity.whitelist* property, which is the only URLs that can be reached using XML Entity processing property. To learn more, see Restrict XML external entities.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.stax.whitelist_enabled*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	This remediation control must be enabled to defend against an XML Entity Expansion/Billion Laugh attack.
Recommended value	true
Default value	true
Security risk rating	9.8
Functional impact	If the customization is using entity expansion, then, the ServiceNow AI Platform might block further processing.
Security risk	An attacker can use this vulnerability to expand data exponentially in an External Entities Expansion (XXE) attack, quickly consuming all system resources.
Workaround	If the customization requires entity expansion, set this property to true and follow the steps documented in Restrict XML external entities.

To learn more about adding or creating a system property, see Add a system property.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

For more information about OWASp resources, see OWASp.

Sanitize All Translated HTML Fields

Learn how to configure the *glide.translated_html.sanitize_all_fields* property to the secure value to ensure that all *translated_html* elements are sanitized with an HTML sanitizer.

When the *glide.translated_html.sanitize_all_fields* system property is set to the value **true**, all translated_html elements will be sanitized using an HTML sanitizer. When the property is set to **false**, an element will only be sanitized if a dictionary attribute, *html_sanitize*, is set to **true**.

Ensure that the Glide Property *glide.translated_html.sanitize_all_fields* is set to the value **true**.

More information

Attribute	Description
Configuration name	*glide.translated_html.sanitize_all_fields*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 4.6 • CVSS score: Medium • Security risk details: Sanitizing HTML elements is a general guideline to ensure an attacker can't embed malicious content that may lead to Cross Site Scripting (XSS) attacks.
Dependencies and prerequisites	None
Functional impact	Allows users to access any table information if the widget is set to public and included in the property's value.

Sanitize HTML in the Description Fields of the Impact Workspace Module [New in Security Center 7.0]

Sanitize the HTML in the description fields by removing HTML tags that are sources of HTML injection attacks with the *sn_impact_common.blacklist_tags_HTML_injection* property.

The Impact Workspace module allows HTML in the following description fields:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- The customer_notes field of the sn_impact_common_capabilities_map and sn_impact_common_par_version_phase_app_mapping tables.
- The manual_description field of the sn_impact_common_manual_capability_description table.

When this system property contains a comma-separated list of HTML tags (for example, scripts), those tags and their contents are removed from the HTML portions of the listed fields. Removing these tags helps sanitize the HTML in the description fields by removing HTML tags that are sources of HTML injection attacks. If this property isn't set in the System Properties [sys_properties] table, the value defaults to a default list of denied HTML tags. If the property is empty, all HTML tags are allowed.

Use the *sn_impact_common.blacklist_tags_HTML_injection* provide a comma-separated list of HTML tags which are removed from the description fields for the Impact Workspace module. This removal helps to prevent HTML injection attacks. At minimum, this list should contain the contents of the default list. If the property isn't set in the System Properties [sys_properties] table, it defaults to the list `script,iframe,object,embed,form,onerror,onload,style,img,video,audio,source,b`

More information

Attribute	Description
Property name	*sn_impact_common.blacklist_tags_HTML_injection*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	Sanitize the HTML in the description fields by removing HTML tags that are sources of HTML injection attacks.
Recommended value	At minimum, the default value of `script,iframe,object,embed,form,onerror,onload,sty`
Default value	`script,iframe,object,embed,form,onerror,onload,sty`
Security risk rating	4.4
Functional impact	If an HTML tag is added to default list, it may limit the required HTML functionality of the description fields. The exact impact is dependent on the customer instance.
Security risk	(Medium)
References	High Security Settings

To learn more about adding or creating a system property, see Add a system property.

Set safe content security policy for SVG files

The *com.glide.csp.self_script_src_svg* property adds the **script-src none** directive to the HTTP Content-Security-Policy header when Scalable Vector Graphics (SVGs) are accessed through the Translation Memory Index (IIX) file extension.

The *com.glide.csp.self_script_src_svg* system property adds **script-src none** to the Content-Security-Policy header when SVGs are accessed via the IIX file extension. This prevents the exploitation of stored XSS from crafted file attachments stored within the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Ensure that the property *com.glide.csp.self_script_src_svg* is set to **true**.

Warning: This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*com.glide.csp.self_script_src_svg*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 7.1 • CVSS score: High • Security risk details: Without this policy, attackers can inject malicious JavaScript that users unknowingly execute, leading to data exfiltration or session takeover.
Dependencies and prerequisites	None
Functional impact	This property prevents scalable vector graphics (SVG) files from accessing external scripts.

Validate MIME type for multi-extension filenames and polyglot files

Use a system property to prevent attachments from bypassing MIME-type restrictions.

Use the *glide.attachment.enable_secure_filename_validation* system property to enable strict validation of attachment file names. When set to true, this property prevents attachments from bypassing MIME-type restrictions. The platform performs full file name sanitization and rejects unsafe patterns that could otherwise be used to upload malicious files.

Add a record to the System Properties [sys_properties] table with the name `glide.attachment.enable_secure_filename_validation` and a value of `true`.

More information

Attribute	Description
Configuration name	*glide.attachment.enable_secure_filename_validation*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Recommended value	true
Default value	false
Fallback value	false
Category	Validation, sanitization, and encoding
Security risk	• Severity score:4.6 • CVSS score: Medium • Security risk details: MIME type validation for file attachments doesn't take place in multi-extension processing or when null bytes are present. This allows attackers to circumvent the *glide.attachment.extensions* and *glide.security.file.mime_type.validation* system properties through null-byte injection, multi-extension file names and polyglot files, leading to malicious file uploads.
Functional impact	When the *glide.attachment.enable_secure_filename_validation* property is set to true: • Uploads that previously passed may now be rejected. • Integrations or automations that rely on generating file names with multiple dots or unusual patterns may fail until updated. • Custom UI pages, scoped apps, or API consumers that upload files programmatically (especially with templated file names) may see validation errors. • CI/CD pipelines that import files, ATF tests, or legacy scripts may need updates to confirm conforming file names. Functionality that does not rely on unsafe file name patterns continue to work normally.
Dependencies and prerequisites	None

Log Export Service (LES)

Log Export Service (LES) lets you seamlessly export your instance system and application logs into your enterprise security analytic tools.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Get started

Explore	Configure	Administer
		
Learn about Log Export Service (LES)	Configure LES for Kafka and MID server consumers	Administering LES

Use	Reference	
		
Review log reports using LES	Learn about miscellaneous information about the app	

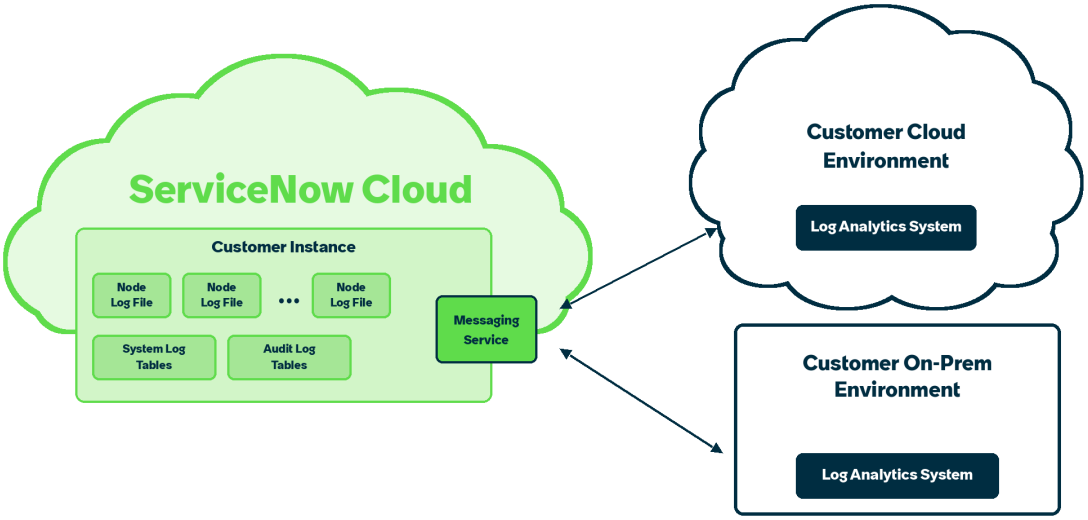
Troubleshoot and get help

- Ask or answer questions about Log Export Service (LES) in the ServiceNow Community
- Search the Known Error Portal for known error articles
- For cloning recommendations for LES, including tables to preserve and exclude, see Tables to be preserved to keep the LES configuration.

Exploring Log Export Service (LES)

LES provides scalable, near real-time integration with analytic tools for security threat detection, performance optimization, and user experience monitoring. If you're new to LES, read this overview section to learn what the tool can do

Verify your entitlements to confirm you have access to Log Export Service.



Log Export Service overview

LES enables you to use your analytic solutions to:

- Detect ServiceNowsecurity threats and analyze security incidents
- Troubleshoot and optimize ServiceNow application performance
- Monitor and optimize ServiceNow user experience

LES leverages Hermes Messaging Service, a multi-tenant, multi-cluster data transport and queuing service built on Apache Kafka. This ServiceNow AI Platform capability enables your instance to produce and consume large volumes of Kafka events. Apache Kafka is an open-source data streaming platform that provides a single integration point for exchanging data across business systems.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

LES forwards a copy of the log events as they are generated to Hermes Messaging Service. Hermes Messaging Service is available as part of Stream Connect, Log Export Service, and Instance Data Replication (IDR).

External log analytic systems, either in the cloud or on-premises, can consume the log events from Hermes Messaging Service. LES provides three connectivity options:

- Dedicated MID Server: A dedicated MID Server installed on-premises or in the cloud automatically connects to Hermes Messaging Service, pulls log events continuously, and pushes them to log analytic tools through a REST connection.
- Kafka connector from your log analytic solution: A Kafka connector from your log analytics product (for example, Splunk) installed on-premises or in the cloud automatically connects to Hermes Messaging Service, pulls log events continuously, and pushes them to log analytics tools.
- Direct Kafka system connection: Your Kafka system connects directly with Hermes Messaging Service and uses native Kafka protocol commands to pull log events.

Note: If your Kafka message exceeds the configured memory buffer, Hermes returns an error indicating the message is larger than the configured total memory buffer.

To configure and manage LES, install it from ServiceNow Store. The LES application provides Guided Setups to install the service, pages to configure the service (log sources, consumers, and destinations), and reports to understand log creation and consumption.

Note: To create a custom source configuration, see Create a log source configuration.

Log Export Service users

The following roles can use LES.

LES user roles

Role	Description
Application admin (sn_logstoanalytics.admin)	The LES application installs this role, allowing non-admin users to configure and manage LES.
System administrator (admin)	Required to install the LES Store application.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Log Export Service benefits

LES benefits and features

Benefit	Feature	User
Create log source configuration to set filters on the logs	Create a log source configuration	Application admin
Experience guided setup for Kafka consumers	Guided setup for Kafka consumers	System administrator
Experience guided setup for MID server consumers	Guided setup for MID Server consumers	System administrator
Examine the log report dashboard to analyze the size of each data log	Review log report	System administrator or Application admin
Replay historical log data from a supported table to backfill downstream systems retroactively	Export existing logs on demand	Application admin or System administrator

What to explore next

To learn more about using Log Export Service, see:

- Administering Log Export Service (LES)
- Configuring Log Export Service (LES)
- Using Log Export Service (LES)
- Log Export Service (LES) references

Log sources

Log Export Service (LES) can export log sources from some System Log Tables, Audit Tables, and Application Node Log Files.

LES can export the following log sources:

- System Log Tables
  - *syslog*: Warnings and errors for instance processes, records, and non-critical events such as memory usage
  - *syslog_transaction*: View all browser activity for an instance
  - *sys_outbound_http_log*: View all requests and responses for outbound web services such as REST and SOAP
- Audit tables
  - *sys_audit*: Record changes made to tables chosen to be audited
  - *sys_audit_delete*: Snapshots produced when audited records are deleted
  - *sys_audit_relation*: Changes to tracked reference fields on audited records
- Workflow/Process logs: *sys_flow_log* records execution details and status of workflow processes

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Security and authentication logs: *sys_user_login_history* tracks user login attempts and authentication events
- Application node log files: Use the localhost log files to view application node errors. Your instance has multiple nodes and each node has multiple log files.

These log sources provide comprehensive visibility into system operations, user activity, and integration points. Export these logs to external systems for long-term retention, compliance auditing, or security analysis.

For detailed schema information and purposes for each log source, see System logs.

Administering Log Export Service (LES)

Use LES to create log source configurations, manage multi-topics per source type, and run on-demand exports of existing logs.

Create a log source configuration

Regulate and set filters on the logs to be forwarded by creating a log source configuration.

Before you begin

Role required: admin or sn_logstoanalytics.admin

Procedure

1. Navigate to **All** > **Log Export Service** > **Sources**.
   A list of source configurations shows up.
2. Select **New** to create a new source configuration.
   You can also select an existing source configuration if you want to modify it.
   The Source form shows up.
3. On the form, fill up the fields.

Source form

Fields	Description
Source Type	Types of log sources ○ Node Log ○ Table See Log sources for more information.
Log Level	A set of standard logging levels that can be used to control logging output. Following convention, each level will forward logs of equal or greater severity. **Note:** This field is visible only when one of the following conditions is met. ○ When you select Node Log as the Source Type ○ When you select Table as the Source Type and the table is syslog

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Fields	Description
Table	Selection of table for exporting table type logs. For more information on supported tables, see Log sources. **Note:** This field is visible only when you select Table as the Source Type.
Filter Type	Conditions to forward logs selectively. **Note:** This field is visible only if you select syslog, sys_audit, sys_audit_delete, or sys_audit_relation as the table.
Topic	Select an existing topic, or create a topic through the lookup icon. For more information on creating a topic, refer Create source type and multi topics in the LES source table
Accepts	Specifies the format in which the logs are forwarded to Hermes. They can either be sent as JSON or as plain text.
Active	Indicates whether the Source log is active.

4. Complete the flow that matches the table you selected.

   - **Standard source**

     Select **Submit** to save the source configuration. The source details appear in the Sources list, where you can review its source type, table, topic, and active status.

     Note:

     - Applies when you select Source type as Node Log and any table other than the syslog and sys_audit tables.
     - The configuration is complete. Skip the remaining steps.

   - **syslog table**

     When you select **Source type** as Table and syslog in the **Table** field:

     Note: You can create multiple source topics for this selection.

     a. Select the **Log level**.

     b. Select **Submit**. The **Source topics** related list appears, and the log export filters become available.

     c. Select **New** to create a new source topic.

     d. In the **Filter** field, select a value from the dropdown list.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **All**: No additional field appears.
- **Application Family**, **Package**, or **Scope**: A corresponding lookup field appears. Select the lookup icon to select a value.

e. In the **Topic** field, select an existing topic, or create a topic through the lookup icon. For more information on creating a topic, refer Create source type and multi topics in the LES source table.

f. Select **Submit**, and then review the source topics that you created.

- **sys_audit table with the Log table filter**

  When you select the **Table** as sys_audit and **Filter type** as Log table:

  Note: You can create multiple source topics for this selection.

  a. The **Source topics** related list appears, and the log export filters become available.

  b. Select **New** to create a new source topic.

  c. Select the required table in the **Log table** field using the lookup icon.

  d. In the **Topic** field, select an existing topic, or create a topic through the lookup icon. For more information on creating a topic, refer Create source type and multi topics in the LES source table.

  e. Select **Submit**, and then review the source topics that you created.

Create source type and multi topics in the LES source table

Consume logs for each source type by creating multiple topics per source type. You can now leverage the option of customized selection of specific topics for different log sources during the debugging process, without impacting the other log tables.

Before you begin

You can create multiple topics only when you select **syslog** as the table, or when you select Table as **sys_audit** and Filter type as **Log table**.

Role required: admin or sn_logstoanalytics.admin

Before you begin

Role required: admin or sn_logstoanalytics.admin

About this task

Multiple topics allow you to organize log consumption by source type. Each source type can have its own dedicated topic, enabling you to debug specific log sources without affecting other log tables.

When you delete a log source, the corresponding topic in the sys_kafka_topic table is retained. If you recreate the log source, you can reuse the existing topic.

Procedure

1. Navigate to **All** > **Log Export Service (LES)** > **Sources**.
2. Click **New** to create a new source.
   The Source form shows up. Previously, the **Topic** field was auto-filled once the **Source Type** was selected. Starting Yokohama, each source type can create their own topic. It doesn't populate by default on selecting the **Source Type** or the **Table** name. They can be created either directly from the Kafka topics or from the reference field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note: Since sys_audit table has multiple log tables, no specific topic is shown in the Topic column of the Sources list. Previously, all the source types had the same topic. Now you can select different topics for different sources.

3. Select the lookup icon to go to the list of Kafka topics.
   The list of Kafka topics shows up.
4. **Optional:** Create the new Kafka topic with the following steps.

   Note: This step is applicable only if you want to create a new topic for a selected Source Type.

   a. Select **New** to create a new Kafka topic for the selected Source Type. The Kafka topic form shows up.
   b. On the form, fill up the fields.

Source form

Fields	Description
Name	Name of the topic you are creating
Application ID	Enter sn_logstoanalytics
Namespace	Enter Default Namespace
Partition	The partition field of a topic in Hermes refers to the partitions into which the topic's data is divided. It plays a key role in scalability and parallelism. Enter 4 as the value for partition.

   c. Select **Submit** to create the new Kafka topic.
5. Select the **Source Type** you want to create for a particular topic.
6. Select the required topic from the list for the selected **Source Type**.
7. Select **Submit** to create the source type with the particular selections.
   The source type shows up on the Sources list with the selected topic name and other information.

Export existing logs on demand

Replay historical log data from a supported table to a Hermes topic by creating and starting a Backfill Run. Use this process to export logs from a specific time range for analysis or archival.

Before you begin

Role required: admin or sn_logstoanalytics.admin

Before you begin:

- Verify that the source table is present in the LES Sources allow-list.
- Verify that the target topic belongs to the LES application scope.

About this task

By default, Log Export Service forwards a copy of log events to Hermes Messaging Service as those events are generated. Use a backfill run to replay historical rows from a supported log table for a bounded time range.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Each Backfill Run replays rows from one source table into one Hermes Messaging Service topic, in ordered batches. Only one active run per table is allowed at a time. After you start a run, its configuration is locked to prevent accidental edits.

Procedure

1. Navigate to **All** > **Log Export Service (LES)** > **Export Historical Data**.
2. Select **New**.
3. On the form, fill in the fields.

Backfill Run form

Field	Description
Name	Name of the Backfill Run.
Table	Log source table whose historical rows you want to replay. For more information on supported tables, see Log Sources.
Log level	A set of standard logging levels that can be used to control logging output. Each level forwards logs of equal or greater severity. Log level options: ○ INFO - Forwards all logs ○ WARN - Forwards warnings and errors ○ ERROR - Forwards errors only **Note:** This field appears only when you select Table as the Source Type and the table is syslog.
Topic	Reference to the Hermes Messaging Service topic that the run publishes to. Select an existing topic, or create a topic through the lookup icon. For more information on creating a topic, see Create source type and multi topics in the LES source table.
Range Start	Earliest timestamp of the historical window to replay. Rows with a timestamp on or after Range Start are included.
Range End	Latest timestamp of the historical window to replay. Range End can be any time up to now and must be equal to or later than Range Start.
Max Rows	Optional cap on the total number of rows the run publishes. Leave blank to publish all rows in the range.
Batch Size	Number of rows the worker publishes per batch. The default is 1000.
Throttle Ms	Optional wait time, in milliseconds, between batches. The default is 0. Increase this value only when the source instance is under heavy load. Typical non-zero values range from 10 to 100 milliseconds.
Active	Indicates whether the Backfill Run is active.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Status	Current state of the run: **New**, **Queued**, **Running**, **Completed**, **Error**, or **Cancelled**. A background scheduler picks up queued runs approximately once every minute.
Status Detail	Plain-language summary of the current state.
Rows Published	Number of rows successfully published to the topic since the run started.
Rows Failed	Number of rows that failed to publish.
First Timestamp Sent	Timestamp of the first row published in this run. Set once when the run starts and does not change.
Last Timestamp Sent	Timestamp of the most recent row published. Updates as the run progresses.
First Sys Id Sent	Sys ID of the first row published in this run.
Last Sys Id Sent	Sys ID of the most recent row published.
Resolved Topic	Reference to the topic record that the **Topic** field resolved to.

4. Select **Submit**.
   The **Status** field is set to **New**.
5. Open the record and select **Start**.
   The **Status** field changes to **Queued** and then to **Running** when the scheduled worker picks it up. All input fields become read-only.
6. **Optional:** To stop a run that has not finished, select **Cancel** while the **Status** is **Queued** or **Running**.

Result

When the run finishes, the **Status** field is set to **Completed** and the **Status Detail** field displays a summary such as "Backfill completed: forwarded 12,345 rows from syslog." If the run stops because of an error, the **Status** field is set to **Error** and the **Status Detail** field describes the cause.

You can also verify that logs are published to the topic using the Hermes topic inspector. For more information, see View a message in a Hermes topic.

Update system property

Update the glide.les.disable_logs_forwarding system property within the Log Export Service application to control log forwarding during migration or database reseeding operations.

Before you begin

Role required: admin

About this task

This property controls whether log forwarding is active in Log Export Service. By default, the value is set to **false**, meaning logs are forwarded normally. During database reseeding or migration, historical log records can be replayed or reprocessed, which may result in duplicate log exports to downstream systems. To prevent duplicate logs from being sent, set this property to **true** to temporarily pause LES forwarding. After the migration is complete, revert the value to **false** to resume normal operation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Log Export Service** > **Sources**.
2. In the workspace filter navigator, enter *sys_properties.list* to access the system properties list.
   This opens the full list of system properties.
3. In the Name column, search for *glide.les.disable_logs_forwarding*.
   In case you do not find the property *glide.les.disable_logs_forwarding*, you can create a new system property by following these steps:

   a. Select **New** on the top-right corner of your screen to create new system property.

   b. In the **Name** field enter *glide.les.disable_logs_forwarding*.

   c. In the **Type** field, select **true | false**.
   Only the **Name** and **Type** fields are required. All other fields are optional and can be left empty.

4. Open the record.
5. The default value is **false**, which means log forwarding is active.
6. In the **Value** field, set the value based on your requirement:

Property	Value	When to use
glide.les.disable_logs_forwarding	**true**	During migration or DB reseeding, this disables log forwarding.
glide.les.disable_logs_forwarding	**false**	Default. After migration is complete, this re-enables log forwarding.

7. Select **Update** to save the change.

Result

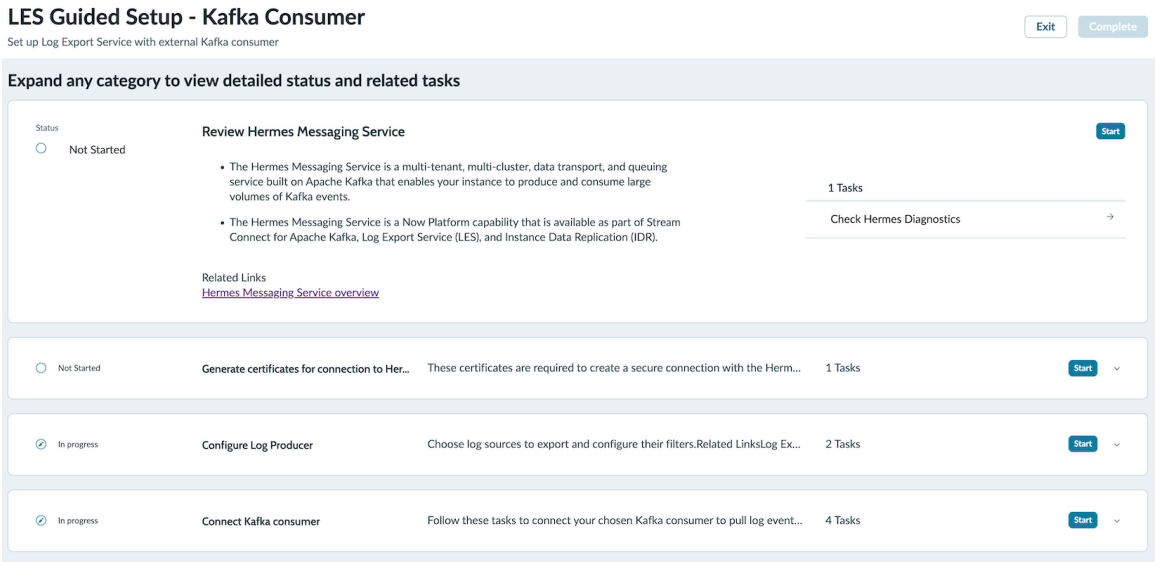
When the property is set to **true**, Log Export Service stops forwarding logs, ensuring no data is sent during a migration or DB reseeding event. Once the operation is complete and the value is reverted to **false**, log forwarding resumes automatically. This configuration allows administrators to safely pause log forwarding during maintenance windows without affecting the underlying LES configuration.

⚠ **Warning:** After migration or database reseeding is complete, revert the property value to **false**. If you do not revert this setting, log forwarding stops permanently and may result in missing log data in downstream systems.

Configuring Log Export Service (LES)

Use guided setup to step through the initial configuration of LES. Guided setup assists you with planning the roll-out of the product and performing the basic configuration to go live.

Guided setup organizes configuration activities into categories. Each category provides information, such as planning guidance, pre-setup steps, and links to useful help content. Categories also provide a set of links to the pages in your instance where you perform the configuration. The guided setup process keeps track of what you have completed, so you can stop and start again where you left off.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Kafka consumer

Use guided setup to step through the initial configuration of LES for Kafka consumers.

Guided setup home page

The home page contains an overview and descriptions of the categories and associated tasks. You can click either the drop down arrow to view information about the category or the Start button to open the guided setup steps and begin configuration. To modify or resume a configuration that you have started, select **Edit** or **Resume**.

Complete the tasks under each category by following the setup instructions.

Guided setup for Kafka consumers

Implement the following steps for a complete guided setup for Kafka consumers.

Before you begin

Navigate to **All** > **Log Export Service (LES)** > **Kafka Consumer** > **Guided Setup**.

Role required: admin

Note: During the Log Export Service application installation, ServiceNow will provision the underlying Hermes Messaging Service infrastructure. Be aware that this process can take up to a couple of hours to complete from the time you request the Log Export Service application installation.

Procedure

1. Review Hermes Messaging Service Diagnostics.

   It is recommended that you verify that the Hermes Messaging Service is up and running with the Hermes diagnostic tool, which displays on screen during this step. If you see a "Page not found" error on this page, Hermes is not installed and you should contact your system admin. For more information, see Exploring Hermes Messaging Service.

   a. Select **Start** to begin.

   b. Review the following diagnostics:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Setup information: The following bootstrap information is used to connect to the Hermes Messaging Service. The "Producer Bootstrap" is the connection used to send messages into Hermes and "Consumer Bootstrap 1 & 2" are used to retrieve messages from Hermes.
  - Producer Bootstrap
  - Consumer Bootstrap 1
  - Consumer Bootstrap 2
- Instance PKI: The Instance Public Key Infrastructure (PKI) component allows a ServiceNow instance to act as an issuer in a X.509 trust hierarchy.
- Bootstrap Connectivity: Select **Run Test** to confirm external client is able to connect to the defined instance ports (producer and consumer).
- Instance Connectivity: Select **Run Test** to confirm the instance is able to send and receive messages.
- View Topics: Select **Get Topic List** to view and retrieve the timestamp of the last known message.

c. Select **Mark as complete** to proceed once done.

Note: You can access Hermes Diagnostics in the future to troubleshoot potential connectivity issues by returning to this step of the guided setup or by navigating to **All** > *Hermes Messaging Service* > **Diagnostics**.

2. Generate certificates for a secure connection to Hermes Messaging Service and pull log events from it.

You are going to use these certificates when connecting your external system.

Set up a secure connection to Hermes Messaging Service. See Set up a secure connection to the Hermes Messaging Service for LES for more information. You will need these certificates for authentication and authorization in the client which will pull the logs from Hermes.

Note: admin or Hermes_admin roles are required for this step.

Select **Mark as complete** to proceed once done.

3. Configure Log Producer: Choose log sources to export and configure their filters. Complete the following tasks to configure the Log Producer.

- Configure log sources to export: Create one Source record for each of the log sources that you want to export.

Note: admin or sn_logstoanalytics.admin roles are required to complete this step.

a. Select **New** to create a new source configuration. The Source form shows up.

Note: You can also select an existing source configuration if you want to modify it.

b. On the form, fill in the fields:

- **Source Type**: Types of log sources (Node Log or Table). See Log sources for more information.
- **Log Level**: A set of standard logging levels that can be used to control logging output. Following convention, each level forwards logs of equal or greater severity. This field is visible when you select Node Log as the Source Type, or when you select Table as the Source Type and the table is syslog.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Table**: Selection of table for exporting table type logs. For more information on supported tables, see Log Sources.
- **Filter Type**: Conditions to forward logs selectively. This field is visible only if you select syslog, sys_audit, sys_audit_delete, or sys_audit_relation as the table.
- **Topic**: Select an existing topic, or create a topic through the lookup icon. For more information on creating a topic, see Create source type and multiple topics in the LES source table.
- **Accepts**: Specifies the format in which the logs are forwarded to Hermes. They can either be sent as JSON or as plain text.
- **Active**: Indicates whether the Source log is active.

c. Complete the flow that matches the table you selected.

- **Standard source**

  Select **Submit** to save the source configuration. The source details appear in the Sources list, where you can review its source type, table, topic, and active status.

  Note:
  - Applies when you select Source type as Node Log and any table other than the syslog and sys_audit tables.
  - The configuration is complete. Skip the remaining steps.

- **syslog table**

  When you select **Source type** as Table and syslog in the **Table** field:

  Note: You can create multiple source topics for this selection.

  i. Select the **Log level**.

  ii. Select **Submit**. The **Source topics** related list appears, and the log export filters become available.

  iii. Select **New** to create a new source topic.

  iv. In the **Filter** field, select a value from the dropdown list.
  - **All**: No additional field appears.
  - **Application Family**, **Package**, or **Scope**: A corresponding lookup field appears. Select the lookup icon to select a value.

  v. In the **Topic** field, select an existing topic, or create a topic through the lookup icon. For more information on creating a topic, refer Create source type and multi topics in the LES source table.

  vi. Select **Submit**, and then review the source topics that you created.

- **sys_audit table with the Log table filter**

  When you select the **Table** as sys_audit and **Filter type** as Log table:

  Note: You can create multiple source topics for this selection.

  i. The **Source topics** related list appears, and the log export filters become available.

  ii. Select **New** to create a new source topic.

  iii. Select the required table in the **Log table** field using the lookup icon.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

iv. In the **Topic** field, select an existing topic, or create a topic through the lookup icon. For more information on creating a topic, refer Create source type and multi topics in the LES source table.

v. Select **Submit**, and then review the source topics that you created.

When successfully created, it will display the name of the Hermes topic to which that log source will be exported to. Write down the topic name, you will need it later when configuring your log consumer system.

The Active field controls whether or not that log source is going to be exported. If you see errors, go back to the Check Hermes Diagnostics task and verify Hermes status.

- Validate Log Producer: Once you have created a Source to produce logs from, you can see live log records in the topic using **Hermes Messaging Service** > **Hermes Topic Inspector**.

  a. Select External Topics

  b. Select List Topics

  c. Select row with your topic from previous step (listed in Sources)

  d. Adjust message start date if necessary

  e. Select **View** to see a log message that was exported to the topic

Select **Mark as complete** once done.

4. Connect Kafka consumer: Follow these tasks to connect your chosen Kafka consumer to pull log events from the Hermes.
   - Identify Kafka consumer: You have two options based on your log analytics architecture.
     - If you have your own Kafka system and choose that for log aggregation, you can connect directly to the Hermes Messaging Service via the native Kafka protocol. For more information, see Apache Kafka.
     - If you choose to have your log analytics tool connect directly to the Hermes Messaging Service, you need to deploy a Kafka connector. Deploy a connector supported by your log analytics system, for example, Splunk Connect for Kafka. For more information, see Splunk Connect for Kafka.

     Note: In either case, you will need to work with the Administrator for those systems to coordinate the connection with the Hermes Messaging Service.

     Select **Next** to proceed.

   - Import Hermes certificates to Kafka consumer system: Log into your Kafka consumer system and make sure you have appropriate admin entitlements to configure it and connect it to an external system. Import the certificates generated in “Set up secure connection to Hermes Messaging Service” task into your Kafka connector or Kafka server. Follow the instructions in the documentation for your chosen Kafka consumer.

     Select **Next** to proceed.

   - Configure Kafka processes: The Hermes Messaging Service is designed for high availability. Two processes are required to consume messages from Hermes. Two processes are required because Hermes uses a pair of Kafka clusters for failover purposes. If one cluster goes down, data is produced to the other Hermes Kafka cluster.

     In your Kafka consumer system, you will need to create two separate consumer processes to connect to both Hermes Kafka clusters. For both processes you will specify the same Hermes Kafka topic but you will need to configure two separate bootstrap addresses:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- <instance_name>.service-now.com:4100,<instance_name>.service-now.com:4101,<instance_name>.service-now.com:4102,<instance_name>.service-now.com:4103
- <instance_name>.service-now.com:4200,<instance_name>.service-now.com:4201,<instance_name>.service-now.com:4202,<instance_name>.service-now.com:4203

Note: Work with your network administrator to ensure that the following port ranges are open before you begin:

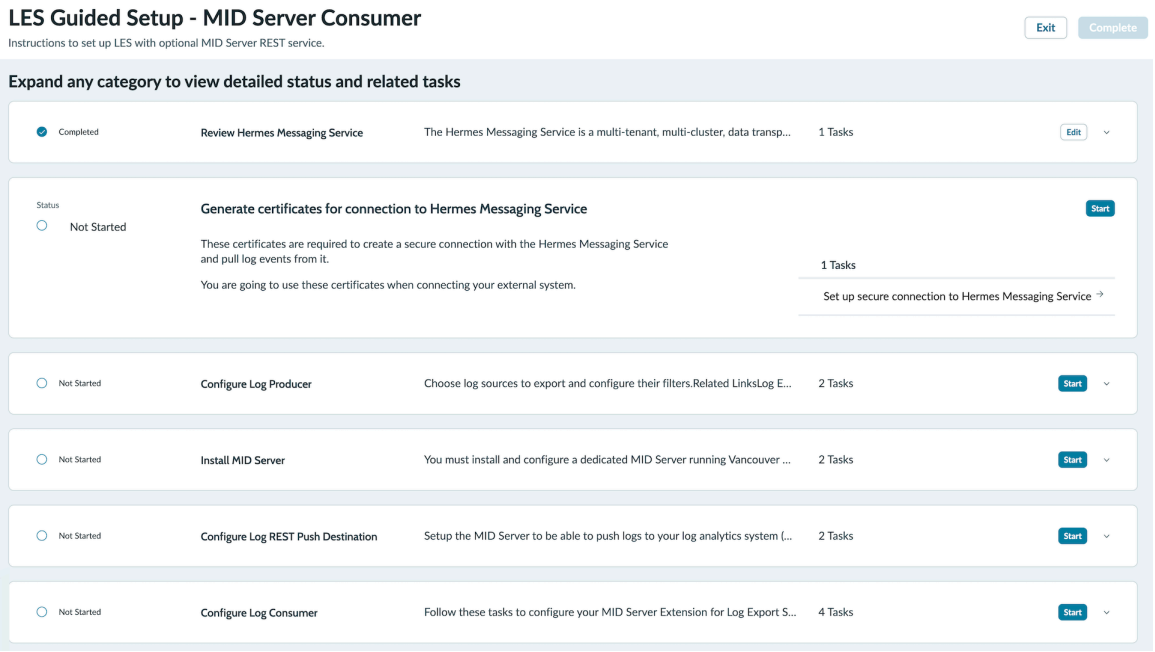
- Consumer1: 4100-4150
- Consumer2: 4200-4250

Important notes:

- When accessing the Kafka topic from external systems, you must prepend “snc.<instance name>.” to the topic that the logs are being forwarded to.
- Configure each consumer with the same Kafka Consumer Group ID.
- Install your keystore and truststore files in a location where your consumers can access them.
- If your consumers require it, specify the Kafka JSON Converters properties to disable schemas: “key.converter.schemas.enable=false”, “value.converter.schemas.enable=false”

- Verify Kafka consumer pulling logs from Hermes: Verify in your chosen Kakfa consumer that you can pull log events from the Hermes Messaging Service.

Select **Mark as complete** once done.



MID server consumer

Use guided setup to step through the initial configuration of LES for MID server consumer.

Guided setup categories page

The categories page contains an overview and descriptions of the categories and associated tasks. You can click either the drop down arrow to view information about the category or click **Start** to open the guided setup steps and begin configuration. To modify or resume a configuration that you have started, select **Edit** or **Resume**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Complete the tasks under each category by following the setup instructions.

Guided setup for MID Server consumers

Implement the following steps for a complete guided setup for MID Server consumers.

Before you begin

Navigate to **All** > **Log Export Service (LES)** > **MID Server Consumer Guided Setup**.

Role required: admin

Note: During the Log Export Service application installation, ServiceNow will provision the underlying Hermes Messaging Service infrastructure. Be aware that this process can take up to a couple of hours to complete from the time you request the Log Export Service application installation.

Procedure

1. Review Hermes Messaging Service Diagnostics.

   It is recommended that you verify that the Hermes Messaging Service is up and running with the Hermes diagnostic tool, which displays on screen during this step. If you see a "Page not found" error on this page, Hermes is not installed and you should contact your system admin. For more information, see Exploring Hermes Messaging Service.

   a. Select **Start** to begin.

   b. Review the following diagnostics:

   - Setup information: The following bootstrap information is used to connect to the Hermes Messaging Service. The "Producer Bootstrap" is the connection used to send messages into Hermes and "Consumer Bootstrap 1 & 2" are used to retrieve messages from Hermes.
     - Producer Bootstrap
     - Consumer Bootstrap 1
     - Consumer Bootstrap 2
   - Instance PKI: The Instance Public Key Infrastructure (PKI) component allows a ServiceNow instance to act as an issuer in a X.509 trust hierarchy.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Bootstrap Connectivity: Select **Run Test** to confirm external client is able to connect to the defined instance ports (producer and consumer).
- Instance Connectivity: Select **Run Test** to confirm the instance is able to send and receive messages.
- View Topics: Select **Get Topic List** to view and retrieve the timestamp of the last known message.

c. Select **Mark as Complete** to proceed once done.

Note: You can access Hermes Diagnostics in the future to troubleshoot potential connectivity issues by returning to this step of the guided setup or by navigating to **All** > *Hermes Messaging Service* > **Diagnostics**.

2. Generate certificates for a secure connection to Hermes Messaging Service and pull log events from it.

You are going to use these certificates when connecting your external system.

Set up a secure connection to Hermes Messaging Service. See Set up a secure connection to the Hermes Messaging Service for LES for more information. You will need these certificates for authentication and authorization in the client which will pull the logs from Hermes.

Note: admin or Hermes_admin roles are required for this step.

Select **Mark as Complete** to proceed once done.

3. Configure Log Producer: Choose log sources to export and configure their filters. Complete the following tasks to configure the Log Producer.

- Configure log sources to export: Create one Source record for each of the log sources that you want to export.

Note: admin or sn_logstoanalytics.admin roles are required to complete this step.

a. Select **New** to create a new source configuration. The Source form shows up.

Note: You can also select an existing source configuration if you want to modify it.

b. On the form, fill in the fields:

- **Source Type**: Types of log sources (Node Log or Table). See Log sources for more information.
- **Log Level**: A set of standard logging levels that can be used to control logging output. Following convention, each level forwards logs of equal or greater severity. This field is visible when you select Node Log as the Source Type, or when you select Table as the Source Type and the table is syslog.
- **Table**: Selection of table for exporting table type logs. For more information on supported tables, see Log Sources.
- **Filter Type**: Conditions to forward logs selectively. This field is visible only if you select syslog, sys_audit, sys_audit_delete, or sys_audit_relation as the table.
- **Topic**: Select an existing topic, or create a topic through the lookup icon. For more information on creating a topic, see Create source type and multiple topics in the LES source table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Accepts**: Specifies the format in which the logs are forwarded to Hermes. They can either be sent as JSON or as plain text.
- **Active**: Indicates whether the Source log is active.

c. Complete the flow that matches the table you selected.

- **Standard source**

  Select **Submit** to save the source configuration. The source details appear in the Sources list, where you can review its source type, table, topic, and active status.

  Note:
  - Applies when you select Source type as Node Log and any table other than the syslog and sys_audit tables.
  - The configuration is complete. Skip the remaining steps.

- **syslog table**

  When you select **Source type** as Table and syslog in the **Table** field:

  Note: You can create multiple source topics for this selection.

  i. Select the **Log level**.

  ii. Select **Submit**. The **Source topics** related list appears, and the log export filters become available.

  iii. Select **New** to create a new source topic.

  iv. In the **Filter** field, select a value from the dropdown list.
  - **All**: No additional field appears.
  - **Application Family**, **Package**, or **Scope**: A corresponding lookup field appears. Select the lookup icon to select a value.

  v. In the **Topic** field, select an existing topic, or create a topic through the lookup icon. For more information on creating a topic, refer Create source type and multi topics in the LES source table.

  vi. Select **Submit**, and then review the source topics that you created.

- **sys_audit table with the Log table filter**

  When you select the **Table** as sys_audit and **Filter type** as Log table:

  Note: You can create multiple source topics for this selection.

  i. The **Source topics** related list appears, and the log export filters become available.

  ii. Select **New** to create a new source topic.

  iii. Select the required table in the **Log table** field using the lookup icon.

  iv. In the **Topic** field, select an existing topic, or create a topic through the lookup icon. For more information on creating a topic, refer Create source type and multi topics in the LES source table.

  v. Select **Submit**, and then review the source topics that you created.

When successfully created, it will display the name of the Hermes topic to which that log source will be exported to. Write down the topic name, you will need it later when configuring your log consumer system.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The Active field controls whether or not that log source is going to be exported. If you see errors, go back to the Check Hermes Diagnostics task and verify Hermes status.

- Validate Log Producer: Once you have created a Source to produce logs from, you can see live log records in the topic using **Hermes Messaging Service** > **Hermes Topic Inspector**.

  a. Select External Topics

  b. Select List Topics

  c. Select row with your topic from previous step (listed in Sources)

  d. Adjust message start date if necessary

  e. Select **View** to see a log message that was exported to the topic

Select **Mark as complete** once done.

4. Configure Log REST Push Destination: Setup the MID Server to be able to push logs to your log analytics system (such as Splunk).
   Complete the following tasks to configure log REST push destination.
   - Add MID Properties: You must add MID Server properties so that it's able to connect to Hermes. Navigate to **MID Server** >**Properties** and set the appropriate values for each of the properties listed below.

Name	Value
mid.les.kafka.ssl.truststore.password	<password>
mid.les.kafka.ssl.keystore.password	<password>
mid.les.kafka.ssl.key.password	<password>
mid.les.kafka.ssl.truststore.location	<your_path>/<truststore>.p12
mid.les.kafka.ssl.keystore.location	<your_path>/<keystore>.p12
mid.les.kafka.ssl.truststore.type	PKCS12
mid.les.kafka.ssl.keystore.type	PKCS12
mid.les.kafka.client.id	<instance_name>
mid.les.kafka.group.id	snc.<instance_name>.group1
mid.les.kafka.bootstrap.servers	<instance_name>.servicenow.com:4100,<instance_name>.se
mid.les.kafka.set2.bootstrap.servers	<instance_name>.servicenow.com:4200,<instance_name>.se
mid.les.consumer.threads.count	4
mid.les.kafka.security.protocol	SSL

Follow these notes on how to obtain some of the above values

- <password> is the password you set for the keystore and truststore
- <your_path> is the file path to the directory where you keep the keystore and truststore files you downloaded. The certificates need to be on the server where you are running MID
- <instance_name> is the name of your ServiceNow instance. If you are not sure, you can find it in the sys_properties table

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- You can obtain the values for both mid.les.kafka.bootstrap.servers and mid.les.kafka.set2.bootstrap.servers from the Hermes Diagnostics page. Navigate to **Hermes Messaging Service** > **Diagnostics** and copy the strings under Consumer Bootstrap 1 and Consumer Bootstrap 2 respectively.

- Configure Destination: Create a new Destination Configuration record, which defines the REST endpoint that this Extension will forward logs to.

  Note: admin or sn_logstoanalytics.admin roles are required to complete this step.

  a. Navigate to **All** > **Log Export Service (LES)** > **Destination Configurations**

  b. Select **New** at the right hand corner.

  c. On the form, fill in the fields:

  - **Name**: Name of the destination configuration.
  - **Destination URL**: The URL for your desired endpoint for the exported log sources.
  - **Destination Credentials**: Search for or create the credentials to connect to your endpoint. Only Basic Auth and OAuth credential types are valid with LES.
  - **Transform Script**: Search for or create a script that specifies how to transform logs into a suitable format for the destination. A predefined script named **SplunkTransform** is provided for Splunk endpoints, which you can use and edit as needed.

  d. Select **Submit**.

5. Configure LOG Consumer: Follow these tasks to configure your MID Server Extension for Log Export Service purposes.

- Configure LES Consumer Context: In this step, you will update the LES Consumer record to execute on the dedicated MID server you just installed for the Log Export Service. Update the LES Consumer record by setting the following fields:

  a. Navigate to **MID Server** > **Extensions** > **LES Consumer Context**.

  b. Select on 'LES Consumer' to open the MID Server context record

  c. Select Specific MID Server for the "Execute on" field

  d. Enter the name of the MID you validated in the previous step for the “MID Server” field

  e. Select **Update**.

  Note:

  - Each Consumer is designed to process data from a single Hermes topic using its own Consumer Context.
  - Each Consumer Context runs on a dedicated MID Server to ensure optimal performance.
  - We recommend configuring a separate MID Server for each Consumer Context you create.

- Configure Consumer: Create a new Consumer record, which represents the process that’s part of the Log Export Service MID Server Extension.

  a. Navigate to **All** > **Log Export Service (LES)** > **Consumers**.

  b. Select **New** to create a new Consumer record.

  c. On the form, fill in the fields:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Name**: Name of the consumer.
- **Topic**: Active topic to retrieve log messages from. Select a topic from the ones available in the Sources table. If the Topic dropdown is empty, navigate to the Sources table and make sure at least one active log source is configured before you create a consumer.
- **Destination Configuration**: Destination to send the retrieved logs to.
- **Consumer Context**: Unique LES Consumer Context record to link to this consumer. Attach the corresponding consumer context when you create the consumer.

d. Select **Submit**.

- Test MID Connection: Verify connectivity from the MID Server environment to the Hermes cluster before starting the Consumer.

Note: Role required: admin or sn_logstoanalytics.admin

Navigate to **Log Export Service (LES)** > **Consumers** and test the connection:

a. Open the existing Consumer record.

b. Click the **Test MID Connection** UI Action

i. This validates connectivity between the MID Server environment and the Hermes cluster

ii. The Status field will change to “Checking Kafka Network Connectivity”

c. Wait for the test to complete, then refresh the page

d. Review the Status and Status Detail fields

e. If successful: Network connectivity is confirmed. Refresh the page and verify the Status and Status Detail fields reflect success.

Start the consumer.

f. If unsuccessful: Please pause before proceeding. Review the MID Server agent logs to understand the cause. Common areas to verify include:

i. MID Server properties are correctly configured

ii. Network connectivity is available between the MID Server and the Hermes cluster

Note: The Test MID Connection must succeed before starting the Consumer.

- Verify MID Server integration:

a. Navigate to#**All** > **Log Export Service (LES)** > **Consumer Status** to view the#Status' and 'Status Detail' fields of the record defined.

The information in these fields reports the current state of the process running on the MID server, including any errors that may have been encountered while relaying messages to the REST endpoint. This is a status view page only.

b. Navigate to **All** > **Log Export Service (LES)** > **Consumers** if you want to create a new consumer record. #If the Consumer status indicates that the process has started, you should be able to inspect your endpoint to view the logs that have been relayed to it. #Additionally, you can view the logs on the MID Server to see if there are additional details

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

about any errors that might be encountered. You can also enable Debug logging on the MID Server to get additional information if needed.

c. Select **Mark as complete** once done.

Note: If you make any change in one of the Consumer records, it shows up on the Consumer Status view page. If you select a consumer record name on the Consumer Status list, the Consumer form for the selected record opens. You can then update the Name and Destination Configuration of the selected record.

Multi-consumer support using unique mid servers

You can now precisely manage log consumption with a new multi-consumer system, enabling dedicated consumers and MID servers for each specific log stream.

The system now supports multi-consumer log consumption which means each log source can be consumed separately have its own dedicated topic.

Previously, all logs were consumed from the same topic. However, with the new multi-topic concept, you can create multiple consumers for different topics. To create a consumer, you can select the following:

- A specific topic from the dropdown menu
- Respective destination configuration
- Respective consumer context

Note: Starting Zurich release, the **Consumer context** is a new field added in the Consumer form. Each consumer context is associated with one unique mid server.

To create multiple consumers, you are required to select distinct topics for each consumer, which in turn would require to create separate consumer context records and its corresponding unique mid servers.

Parallel processing with multiple MID servers

A major benefit of this multi-consumer architecture is the ability to run multiple consumers in parallel. This parallel processing significantly enhances the overall throughput and efficiency of log consumption, allowing the system to handle larger volumes of diverse log data more effectively than before.

Note: For a mid server consumer, the maximum production level throughput is 31500 msg/sec. You can use 27,000 msg/sec as the reliable sustained throughput.

Set up a secure connection to the Hermes Messaging Service for LES

Secure your Kafka topics by generating a ServiceNow® instance-signed certificate.

Before you begin

Setting up the Hermes Messaging Service requires coordination with your network administrator and with your Kafka administrator. Work with your network administrator to obtain required security certificates and open the required ports. Work with your Kafka administrator to ensure that your Kafka environment is configured correctly and that your applications can connect to the Hermes Messaging Service using the standard Kafka protocol.

Make sure the following setup is in place:

- The Hermes Messaging Service is activated. See Activating the Hermes Messaging Service.
- The Key Management Framework plugin (com.glide.kmf.global) is activated.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- The Certificates [sys_kmf_certificate] table contains a ServiceNow instance root CA certificate.
- The instance isn't configured with a Custom URL. Custom URLs are not supported with the Instance PKI Certificate Generator.

Role required: hermes_admin, sn_kmf.cryptographic_manager, or admin

For details on assigning KMF roles, see Roles installed with Key Management Framework.

Procedure

1. Navigate to **All** > **Certificate Generator** > **Instance PKI Certificate Generator**.
2. **Optional:** Control access to topics by configuring Access Control Lists (ACLs) at the namespace or topic-level.

Option	Description
Apply ACLs to namespaces	**a.** Select **Configure ACLs**. **b.** In the Topic ACLs dialog box, select **Name spaces**. **c.** Enter a namespace that you want to config ure. **d.** Set the permission level by selecting either **Read Only** or **Read/Write**. **e.** Select **Add**.
Apply ACLs to defined topics	**a.** Select **Configure ACLs**. **b.** In the Topic ACLs dialog box, select **De fined topics**. **c.** Enter an existing topic that you want to con figure. **d.** Set the permission level by selecting either **Read Only** or **Read/Write**. **e.** Select **Add**.

   The bearer of the certificate is granted read or read/write access to the topics in the namespace or the existing topic that you selected.
3. Set up security for the Hermes Messaging Service.
   a. Navigate back to the Instance PKI Certificate Generator page.
   b. Enter a keystore password in the **Certificate Password** field.
   c. Select **Generate**.
   The system generates an instance-signed certificate in the Certificates [sys_kmf_certificate] table, creates a keystore, and creates a truststore.

   If Restricted Caller Access isn't allowed for the IPKI Certificate Generator, a cross scope access error appears. Contact Customer Service and Support for assistance with allowing Restricted Caller Access. To resolve this issue, Customer Service and Support can reference source_scope=76f9d51369115083f4ea77aab1677cc0 in the Restricted Caller Access Privileges [sys_restricted_caller_access] table.
4. Save a copy of the keystore by selecting **Download Keystore**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

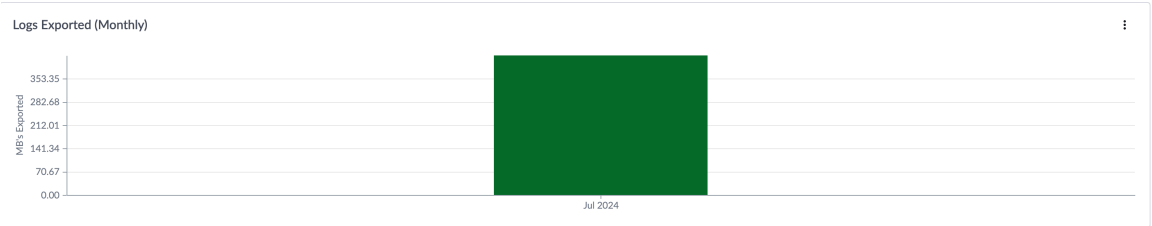
5. Save a copy of the truststore by selecting **Download Truststore**.
6. Copy the keystore and truststore files to each producer and consumer client that will connect to the Hermes Messaging Service.

Result
You can now create a secure connection to the Hermes Messaging Service.

Note: You must use the keystore that you generated using the Instance PKI Certificate Generator to connect to Hermes. Custom-generated keystores that aren't created according to the ServiceNow documentation aren't supported.

What to do next
Check the status of and connection to the Hermes Kafka cluster.

Using Log Export Service (LES)

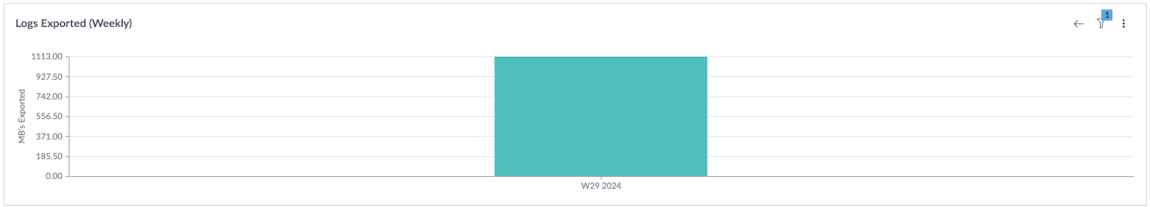


Use LES to review the log report dashboard.

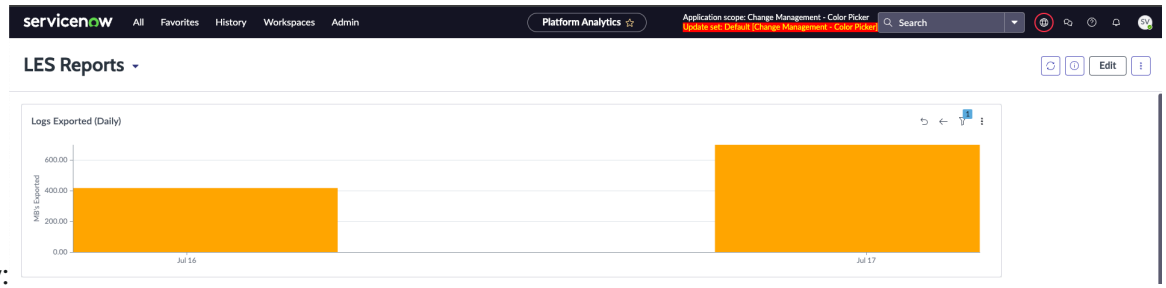
Review log report

Analyze the size of each data log by reviewing the log report dashboard.

Before you begin
Role required: admin or sn_logstoanalytics.admin



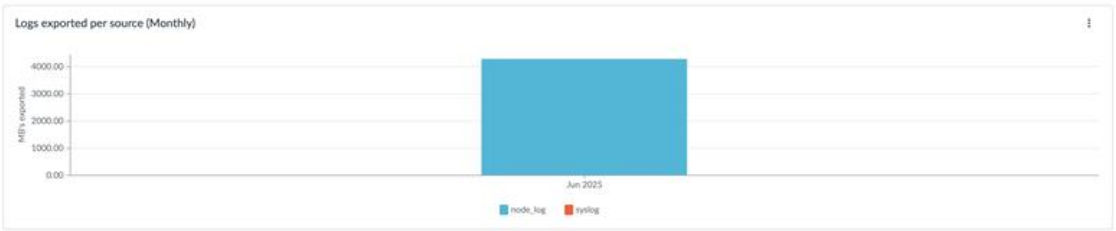
Procedure
1. Navigate to **All** > **Log Export Service** > **Reports**.
2. Review log data in the following widgets.
   - Logs Exported (Monthly): It shows the megabytes exported per month in the initial view. You can drilldown the graph to view the data for each week or daily data. You can view data from last 395 days.



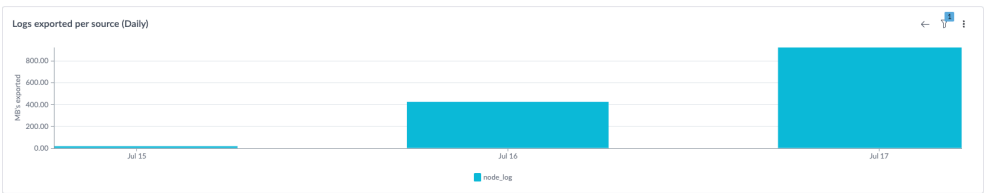
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note: Click on the arrows on the up right corner of the widget to drill down the data. You can also move back up to the parent data.

Weekly:

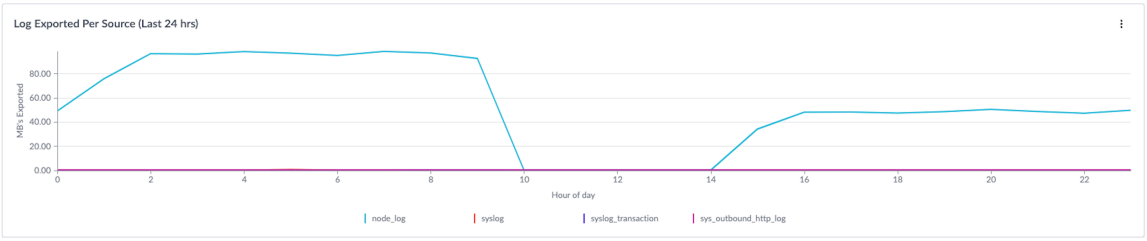


Daily:

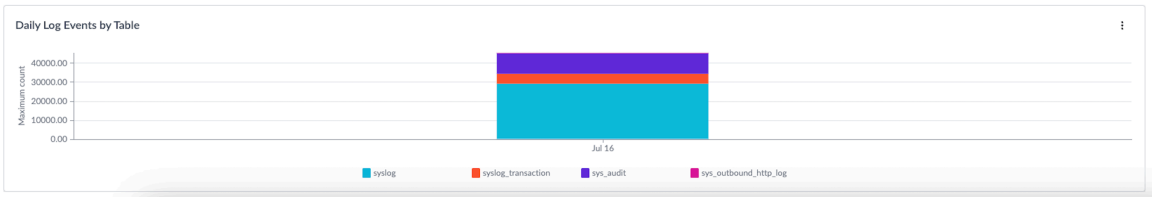


The data in this report reflects collection taken 4 hours prior.

- Logs exported per source (Monthly): This widget shows the kind of logs were exported on a monthly basis. You can also drilldown to see weekly and daily log data. You can view data from last 395 days.



Note: You can select or de-select the source you want to view the data from. The sources from which you can view the logs are: node_log, syslog, syslog_transaction, and sys_outbound_http_log.



- Log Exported Per Source (Last 24 hrs): It shows the data from last 24 hrs. The graph progresses chronologically from left to right on a 24 hr scale, with the oldest data (24th hour) positioned on the right and the latest data on the left side of the report. You can select or de-select the source you want to view the data from. The sources from which you can view the logs are: node_log, syslog, syslog_transaction, and sys_outbound_http_log.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note: Depending on the hour of the day you check this data, the widget dynamically updates to reflect exactly the past 24 hours.

- Daily Log Events by Table: It shows the log events generated by each log tables per day. You can select or de-select the tables you want to view the data from.

Note: The tables from which you can view the log events are: syslog, syslog_transaction, sys_audit, and sys_outbound_http_log.

Log Export Service (LES) references

Find all the miscellaneous information about LES in the reference section.

Log Export Service roles

Log Export Service is installed with these roles.

Application admin [sn_logstoanalytics.admin]

To learn more about managing per-user subscriptions, see Managing per-user subscriptions in Subscription Management and contact your account representative.

This role is installed along with the LES application and allows a non-admin to use the application.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Elevated

Whether the role is an elevated role. Elevated roles aren't assigned to users or groups, and must be used by elevation. For details, seeElevate to a privileged role.

No.

© 2026 ServiceNow, Inc. All rights reserved.

Log Export Service actions and required roles

Log Export Service uses role-based access control to restrict actions to authorized users.

Role-based access control

Log Export Service uses role-based access control so that only authorized users can perform specific actions. The following table maps Log Export Service actions to the roles required to perform them.

Unless otherwise noted, any one of the listed roles is sufficient to perform the action.

Log Export Service roles

Log Export Service includes the following three primary roles:

sn_logstoanalytics.admin

Application administrator role. Installed with the Log Export Service application and allows a non-admin user to configure and use Log Export Service.

admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

System administrator role. Required to install the Log Export Service Store application and to perform platform-level setup tasks.

hermes_admin

Required to generate the certificates that secure the connection between Log Export Service and the Hermes Messaging Service.

Log Export Service actions and required roles

Action	Description	Required roles	Component
Initial setup and configuration			
Install Log Export Service application	Install Log Export Service from the ServiceNow Store.	admin	Instance
Review Hermes Messaging Service diagnostics	Verify that the Hermes Messaging Service is running, check connectivity, and view topics.	admin	Instance
Run Kafka consumer guided setup	Step through the initial configuration of Log Export Service for an external Kafka consumer.	admin	Instance
Run MID Server consumer guided setup	Step through the initial configuration of Log Export Service for a dedicated MID Server consumer.	admin	Instance
Log source configuration			
Create a log source configuration	Regulate and set filters on the logs to be forwarded by creating a source record for each log source.	admin or sn_logstoanalytics.admin	Instance
Create source type and multiple topics	Consume logs for each source type by creating multiple Kafka topics.	admin or sn_logstoanalytics.admin	Instance
Validate Log Producer	View live log records in a topic by using the Hermes Topic Inspector.	admin or sn_logstoanalytics.admin	Instance
Kafka consumer configuration			
Generate certificates for Hermes secure connection	Generate the certificates required to authorize a client	admin or hermes_admin	Instance

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Log Export Service actions and required roles (continued)

Action	Description	Required roles	Component
	that pulls logs from the Hermes Messaging Service.		
Configure Kafka consumer processes	Create consumer processes with separate bootstrap addresses to connect to both Hermes Kafka clusters for failover.	admin	External Kafka
Verify Kafka consumer pulling logs	Verify that the chosen Kafka consumer can pull log events from the Hermes Messaging Service.	admin	External Kafka
MID Server consumer configuration			
Install and validate dedicated MID Server	Install a MID Server dedicated to Log Export Service, and validate it to enable it to execute automation tasks.	admin	Both
Add MID Server properties for Hermes	Configure properties that establish the Kafka connection between the MID Server and the Hermes Messaging Service.	admin	Instance
Configure Log REST push destination	Create a Destination Configuration record that defines the REST endpoint that the MID Server Extension forwards logs to.	admin or sn_logstoanalytics.admin	Instance
Configure LES Consumer Context	Update the LES Consumer MID Server Extension record to execute on the dedicated MID Server installed for Log Export Service.	admin	Instance
Configure Consumer	Create a Consumer record specifying the Hermes topic to retrieve logs from	admin or sn_logstoanalytics.admin	Instance

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Log Export Service actions and required roles (continued)

Action	Description	Required roles	Component
	and the destination configuration to relay them to.		
Test MID Connection	Verify connectivity from the MID Server environment to the Hermes cluster.	admin or sn_logstoanalytics.admin	Instance
Verify MID Server integration	Monitor the Consumer Status view to confirm the MID Server process is relaying messages to the REST endpoint.	admin or sn_logstoanalytics.admin	Instance
Administration and monitoring			
Update the glide.les.disable_logs_forwarding system property	Pause or resume Log Export Service log forwarding during migration or database reseeding operations.	admin	Instance
Review log report dashboard	Analyze the size of each data log and consumption metrics across Log Export Service sources.	admin or sn_logstoanalytics.admin	Instance

Properties installed with Log Export Service

Log Export Service (LES) adds the following instance system properties and MID Server properties.

System properties

Log Export Service adds the following instance system properties.

Property	Type	Description
com.glide.script.glide_record_logger.forward_tables	String	Comma-separated list of tables that Log Export Se tables in this list are available as a source type Tab Source form. Default value: `syslog,sys_outbound_http_log,syslo`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Type	Description
glide.les.disable_logs_forwarding	true | false	Kill switch that turns off Log Export Service auto-co globally. When set to `true`, Log Export Service st Messaging Service. **Important:** If this property does not exist in new property with the same name. For more information, see Update system property Default value: false
glide.les.max_queue_size	Integer	Maximum number of log entries that can wait in th queue. Increase this value if log entries are being volume. Default value: 4096
glide.les.queue_slot_wait_time	Integer	Time in milliseconds that the Log Export Service a asynchronous forwarding queue before dropping the appender doesn't wait and drops the entry im Default value: 0
glide.log.forwarding.num_topic_partitions	Integer	Number of partitions created for each Hermes top produces to. Partitions affect scalability and parall Default value: 4
glide.log.forwarding.syslog.topics.limit	Integer	Maximum number of unique Hermes topics that ca source. Default value: 10
glide.log.les.async_enabled	true | false	Enables asynchronous log forwarding from the ins Service. Asynchronous forwarding reduces the pe under high log volume. Default value: true
sn_logstoanalytics.debug	true | false	Enables verbose debug logging for the Log Export Default value: false **Important:** This property is disabled by def debug logs in node logs.
sn_logstoanalytics.kafka.multi_topics	true | false	When set to `true`, Log Export Service uses a sep type instead of a shared topic, so that downstream specific log sources independently.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Type	Description
		Important: When set to `false`, the ability source table is disabled. Default value: false

MID Server properties

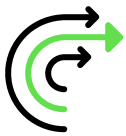
For deployments that use a dedicated MID Server to consume logs from the Hermes Messaging Service, Log Export Service uses the following MID Server properties.

Property	Type	Description
mid.les.consumer.threads.count	Integer	Number of Kafka consumer threads that read from Hermes topics on the MID Server. Controls the number of parallel consumers. Default value: 4
mid.les.kafka.bootstrap.servers	String	Comma-separated list of `host:port` pairs for the primary Hermes Kafka cluster. The default port range is 4100-4150; ensure this range is open between the MID Server and Hermes.
mid.les.kafka.client.id	String	Kafka client identifier the MID Server sends when opening a connection to Hermes. This value appears in Kafka client logs. Set the value to the ServiceNow AI Platform instance name.
mid.les.kafka.enable.auto.commit	true | false	Enables Kafka automatic offset commits. Keep this property set to `false` so that offsets are committed only after successful message processing, which helps prevent data loss if the consumer restarts mid-batch. Default value: false
mid.les.kafka.group.id	String	Kafka consumer group identifier that the MID Server joins when consuming from Hermes. This value must be unique per consumer group. Set the value to `snc.<instance_name>.group1`.
mid.les.kafka.poll.duration.millis	Integer	Time in milliseconds that the consumer waits while polling Kafka for new records. Higher values reduce polling overhead but slightly increase latency. Default value: 1000

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Type	Description
mid.les.kafka.security.protocol	String	Security protocol used for the Kafka connection to Hermes. Log Export Service supports SSL. Set the value to `SSL`.
mid.les.kafka.set2.bootstrap.servers	String	Comma-separated list of `host:port` pairs for the secondary Hermes Kafka cluster, used for high availability and failover. The default port range is 4200-4250.
mid.les.kafka.ssl.key.password	String	Password for the private key stored inside the keystore file.
mid.les.kafka.ssl.keystore.location	String	Absolute file path on the MID Server host to the PKCS12 keystore that contains the MID Server client certificate presented to Hermes. For example, `/opt/mid/certs/mid_keystore.p12`.
mid.les.kafka.ssl.keystore.password	String	Password that unlocks the keystore file specified in *`mid.les.kafka.ssl.keystore.location`*.
mid.les.kafka.ssl.keystore.type	String	Format of the keystore file. Typically `PKCS12`. Default value: PKCS12
mid.les.kafka.ssl.truststore.location	String	Absolute file path on the MID Server host to the PKCS12 truststore that contains the Hermes CA certificates. For example, `/opt/mid/certs/mid_truststore.p12`.
mid.les.kafka.ssl.truststore.password	String	Password that unlocks the truststore file specified in *`mid.les.kafka.ssl.truststore.location`*.
mid.les.kafka.ssl.truststore.type	String	Format of the truststore file. Typically `PKCS12`. Default value: PKCS12
mid.les.metrics.frequency.millis	Integer	Frequency in milliseconds at which the MID Server reports Log Export Service consumer metrics back to the instance. Default value: 60000 (60 seconds)
mid.les.processor.threads.count	Integer	Number of worker threads used to process consumed messages. Can be tuned independently from *`mid.les.consumer.threads.count`* to increase throughput without changing the number of Kafka pollers.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Property	Type	Description
		Default value: 4

Logs

Logs module provides a variety of logs that you can use to troubleshoot and debug transactions and events that take place within the instance.

Get started

System Logs

The System Logs module provides a variety of logs that you can use to troubleshoot and debug transactions and events that take place within the instance.

Logging, auditing, and errors

Apply a logging and auditing strategy so that you can identify and act on suspicious activity in a timely manner.

System logs

The System Logs module provides a variety of logs that you can use to troubleshoot and debug transactions and events that take place within the instance.

Access the following logs from the System Logs module:

Log	Description
Transactions	All application activity for an instance.
Email and Push	All email notifications and Push messages sent from all instances within the system.
Event Logs	All system events that occur within the system.
Import	Data import activity within the platform.
Table Changes	Changes made to all tables in the system.
Outbound web services logging	All outbound web services requests such as REST and SOAP requests.
Signature Images	Electronic signatures for the HR signature pad.
System	Warnings and errors for instance processes, records, and non-critical events, such as memory usage on the server machine.

Use the Log File Browser to search and download logs. You can also search archived logs in the log history.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Other logs

Your instance offers other logs in addition to those in the System Logs module. For example, the System Diagnostics module provides upgrade history and slow query logs, which you can use to gain insight into how queries are affecting platform performance. The Customer Updates table records every change that is made in the system.

System log

View warnings and errors for instance processes, records, and non-critical events, such as memory usage on the server machine.

The following information is tracked in the system log:

- Workflows
- Configuration
- Chats sessions
- Transactions for each view of each page in the system, including load times for network, server, and browser
- Inbound and outbound email
- Events triggered in the system
- Imports and integrations
- System warnings, errors, and script logs
- Upgrade information for any plugin activations, update sets, or system upgrades

Log entries appear for the current day only. To view other log files, use the log file browser.

Syslog messages serve diagnostic and maintenance purposes. Log messages can have different owners and may not require action from all readers. Check the message source to determine relevance and ownership. The following fields describe the attributes of each message.

System log

Field	Description
Created	Date and time of the logging activity for the locale of the machine running the instance.
Level	The severity classification of the message. Levels indicate the nature of the event, not necessarily whether action is required. Messages are generated by the ServiceNow platform, installed applications, and custom scripts. The levels are Debug, Information, Warning, and Error. • Debug: Detailed diagnostic information, typically used during development or active troubleshooting. • Information: Confirmation that an operation completed as expected. • Warning: An unexpected condition was encountered, but the operation completed successfully. May require investigation depending on context and source.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

System log (continued)

Field	Description
	• Error: An operation failed or could not complete as intended. Instances can generate a high volume of Error messages, primarily from the platform itself. These do not necessarily indicate a platform issue and do not always require further investigation.
Message	System-generated message regarding the nature of the occurrence. **Note:** Long messages and stack traces are collapsed by default and can be expanded. To disable, see Disable stack trace formatting in system logs.
Source	Name of the process or area affected by the occurrence. For example, the source of the occurrence might be EMAIL or Memory.
Source Package	Name of the application package associated with the occurrence. Select the name to view the Store Application [sys_store_app] record for this package.

Workflow logging

- Each activity executed, including:
  - Date and time started
  - Date and time ended
  - State, for example, Finished, Cancelled, Timed Out, Error
  - Result
  - Fault description, if there was an error
- Transition history, including:
  - Time of transition
  - Activity transitioned from
  - Activity transitioned to
  - Which transition was triggered
- Workflow log, including any log statements added to the workflow

Configuration information

- Action taken, including insert, update, and delete
- Category of change
- Comments recorded with the change
- Name of the change
- XML difference of the change
- Update set associated with the change
- Date and time of the change
- User who made the change
- Table where the change was made

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Name of the object being changed
- Type of object being changed
- View in which the change was made, for form or list changes

Disable stack trace formatting in system logs

Enable viewing original unformatted log messages by disabling the collapsible stack trace formatting in system logs.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Definition** > **Client Scripts**.
2. In the **Name** field, enter `FormatStackForSyslog`.
3. Select **FormatStackForSyslog**.
4. Clear the **Active** check box.
5. Select **Update**.

Transaction logs

The transaction log records browser activity for an instance. To aid in debugging of system issues, you can filter transaction logs by application scope, limiting transactions that appear to only those transactions originating in specific scopes.

Note: Background and scheduler transactions are logged only when their execution time exceeds 1000ms. For a complete list of logged transactions, see KB0778299.

Access the transaction logs by navigating to **All** > **System Logs** > **Transactions**. The transaction log provides the following information for all activities.

Field	Description
Created	Date and time of the application action for the locale of the machine running the instance.
Type	Type of recorded transaction.
Created by	User who created this activity.
Origin application	Application scope the transaction originated in. Global appears if the transaction originated in the global scope.
Response time	Round trip response time for the application request, in milliseconds.
Network time	Latency time of the network response after the application request is made, in milliseconds.
Output length	Size of the output string sent by the instance to the application, in bytes.
SQL count	Number of SQL server commands executed for this activity.
Business rule count	Number of business rules executed for this activity.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Business rule time	Elapsed time for the execution of the business rules for this activity.
URL	Application or module connected to by the client application.
System ID	System generated identifier of the client instance making the request. This ID is used for cluster environments in which several instances (nodes) communicate with the database.
IP address	IP address of the client making the request.
GZipped	Indication of whether a compressed Web page was requested by the application.
Protocol	HTTP protocol used by the application for this instance.
HTTP Response Code	Status code returned by the server indicating the result of the HTTP request.

Client transaction timings

The Client Transaction Timings plugin enhances the system logs by providing additional information about the durations of transactions taking place between the client and the server.

You can track down performance issues to their source by viewing where the time is being consumed, and how time was spent during a transaction.

This plugin requires the Response Time Indicator Response Time Indicator to be enabled, and collects information from the following browsers:

- Firefox
- Internet Explorer
- Chrome

Client Transactions Information

Installing the plugin adds the *Client Transactions* module to the *System Logs* application. It provides a list of every logged transaction between client and server within the last day:

Client Transactions Information

Field	Description
Created	Moment the transaction was recorded.
Response Time	Number of ms spent by the server in fulfilling the transaction.
Business Rule Time	Number of ms spent by business rules triggered by the transaction.
SQL Time	Number of ms spent by the SQL database.
Client Response Time	(Load_completion_time) - (start_time). It is inclusive of server time.
Client Network Time	Number of ms spent by the network the client is connecting through.
Browser Time	Number of ms spent by the browser during the transaction.
Client Script Time	The number of ms spent executing client scripts.
UI Policy Time	Number of ms spent executing ui policy.
Type	Type of transaction:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Client Transactions Information (continued)

Field	Description
	• Form • List • Other
Table	Name of table that appeared. For example, incident, change_request.
View	View for this form/list.

Client Detailed Information

A more detailed breakdown of the client timings for all Form rendering (but not list rendering) is also tracked. To see details, drill into a particular client transaction record and observe the related list at the base of the screen.

Client Detailed Information

Field	Description
Order	Order during the load in which this operation occurred.
Type	Type of operation.
Name	Descriptive name of this particular operation
Duration	Number of ms this operation took to complete.

Push logs

Consult the push log to track the status of push notifications that are queued to send from your system.

To view the push log, navigate to **System Logs** > **Push Notifications**. Users are required to have the push_admin or admin role to view the push log.

Push log fields

Field	Description
Claim	Identification number that is generated by the scheduled job that sends the push notification. This number is applied to the **Claim** field to ensure consistency across multiple push scheduled jobs.
Payload	Content of the push notification.
Queue count	Number of times that the system tried to send the push notification. The status of the push notification relates to its queue count.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Push log fields (continued)

Field	Description
	• If the queue count is 0 for longer than expected, then there are no scheduled jobs that are trying to send the push notification. • If the queue count is greater than 0 and the **Type** is **success**, then you can infer that this is how many times the system tried to send the push notification before finally sending. • If the queue count reaches 10, the system stops trying to send the push notification. The **Type** changes to **failure**.
Request ID	Unique identification number for the push notification. Similar to the message ID for an email, the request ID is used as a correlation token for the push notification.
Type	Status to indicate whether the push notification has been sent. The Type column can have these values: • **failure**: The message could not be sent. • **pending**: The message is queued for processing. • **success**: The message was successfully sent, although not necessarily received by the mobile device.

Scheduled jobs

System email log and mailboxes

The system email log records all emails that the instance creates or receives. System mailboxes are filtered views of this log.

Every notification email that the instance creates or receives is recorded in an Email [sys_email] record. You can navigate to a log of these records at **System Logs** > **Emails**.

The System Mailboxes are filtered views of the Emails [sys_email] table. The instance assigns an email record to a system mailbox depending on the values of the **Type** and **State** fields. For more information, see System mailboxes.

The following fields can be included in the layout of the system log and any of the system mailboxes:

Email log

Field	Description
Mailbox	The system mailbox that lists this email record. The instance sets the value of this field according to the values of the **Type** and **State** fields.
State	The current state of the email (Error, Ignored, Processed, or Ready).
Receive type	The type of inbound email (None, Forward, New, or Reply).
Type	The status of the email. Choices are:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Email log (continued)

Field	Description
	• received: The server received this email. • received - ignored: The server received this email, but it was ignored by the instance for inbound email action purposes. Typically, these emails are either spam or auto-replies. See the Error String field for details. • send - failed: The server has attempted to send the email and failed. See the Error String field for details. • send - ignored: The server skipped sending this email. Typically, this is for an email which was generated but lacked a recipient email address or is a duplicate email. See the Error String field for details. • send - ready: The email is ready to be sent, but has not been sent out by the mail server. Typically, an email remains in this state for only a short time. • send - translation - ready: The email is generated during email translation and sent out. Typically, an email remains in this state for only a short time. • sent: The email was sent by the instance without any errors or issues.
Target	A Document ID reference to the record if the email is generated by an insert, update, or delete of a particular record.
User	The name of the user, from the user record, of the instance from which the email notification was sent. **Note:** This is a string field.
Notification Type	The type of notification. Choices are: • None • SMS • SMTP
UID	The unique ID of the email stored on the server.
Created	The date and time of the email activity for the locale of the machine running the instance.
Deleted	For inbound email, indicates whether the email was deleted from the email server.
Weight	The weight of the email, which determines the sending priority relative to other notifications on the same table.
Importance	An indication that the email was sent with a changed level of importance, such as Urgent.
Originating Event and Notification	For emails generated by notifications, an embedded list that stores the event and notification that created the email.
Subject	The email subject. For notifications, you create the subject text in **System Notification** > **Email** > **Notifications**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Email log (continued)

Field	Description
Error String	The error string captured from the email server to determine why the email was not sent. This is logged only if the email is send-failed.
Recipients	The email addresses of the recipients.
Body	The body of the email, displayed in raw HTML markup. Use the related link Preview HTML Body to see the body text as rendered HTML.
Content type	The email content type.
Headers	Any headers embedded in the email.

Event logs

The event log records all system events that occur within the ServiceNow AI Platform.

This log provides the following information for all events that occur:

Event log

Field	Description
Created	Date and time of the event for the locale of the machine running the instance.
Name	Name of the event as listed in the Event Registry.
URI	HTTP query that generated the event.
Parm1	Event-specific value that depends on the event and the recipient.
Parm2	Event-specific value that depends on the event and the recipient.
Table	Database table acted on for this event.
Processed	Date and time the event started processing. This time reflects the locale of the machine running the instance.
Processing time	Time taken to process this event, in milliseconds.
Queue	Processor queue name.

Import logs

The import log displays information in a verbose format about any data import activity within the platform.

For a more detailed view of the import sets that produced a particular log, see **Import Sets** > **Transform History**.

This log provides the following information for all imports:

Import log

Field	Description
Created	Date and time of the import for the locale of the machine running the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Import log (continued)

Field	Description
Level	Type of message displayed. For import files, the level is Information.
Message	System-generated message regarding the status of the import.
Source	Name of the external source of the import, such as an integration.

System Diagnostics module

The System Diagnostics application provides logs that relate to the platform.

These logs are available:

Upgrade History

Tracks every upgrade to an instance.

Slow Queries

Provides insight into how queries affect platform performance. See Use a slow query log.

Customer Updates table

Changes made in the system are recorded on the Customer Updates [sys_update_xml] table chronologically. There are a few exceptions, as noted below.

To navigate to this table, enter `sys_update_xml.list` into the navigation filter. For information about update sets, see System update sets.

The following information is stored about each update:

Customer Updates table

Field	Description
Name	A name that identifies the updated record.
Created	The date and time the Customer Update record was created.
Created By	The user who performed the change.
Type	The type of the update.
Updated	The date and time the Customer Update record was updated.
Updated By	The user who performed the update.
Updates	The number of times the record has been updated.
Target Name	The name of the element that was altered.
View	The view of the form that was altered if it was a form layout change.
Payload	The XML contents of the record after the change.
Remote Update Set	A reference to that update set if the change was performed by a remote update set.
Local Update Set	The update set the change is associated with.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note: Some application changes are not represented by Customer Update records (sys_update_xml) Examples:

- Types of metadata where updateSynch = false
- Cascading changes to tables and fields such as display name changes
- Unresolved metadata references from other applications (resulting in no “display value” on the element)
- sys_id changes for coalescing files
- Changes to Flow/Flow Actions that may generate sys_documentation
- ua_table_license_config records generated on table creation
- Jobs running in the background such as natural language processing
- Cases where sys_update_xml is manually modified or removed

To learn more, see Commit changes.

Log history

The system uses table rotation and table extension to archive older logs.

By default, the system uses the following schedule to archive common logs:

Common log archive schedule

Table	Archive schedule	Rotations	Type
Event [ecc_event]	Every day	7	Rotation
Queue [ecc_queue]	Every day	7	Rotation
Event [sysevent]	Every day	7	Rotation
Log [syslog]	Every week	8	Rotation
Transaction Log [syslog_transaction]	Every week	8	Rotation

Note: The Email [sys_email] table is not managed using table rotation or extension. Instead, use the Email retention plugin to archive and destroy email records. By default, email records are archived after one year and destroyed after an additional year in the archive.

Use the log file browser

The instance provides the utilities log file browser and log file download.

Use **System Logs** > **Utilities** > **Node Log File Browser** to view any system log entry. You can search for log files by using the following filters:

Log file browser

Field	Description
Start time	Start date and time of the range you want to search, for the locale of the machine running the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Log file browser (continued)

Field	Description
Session ID	System-generated hexadecimal string that identifies the session that generated the log entry.
End time	End date and time of the range you want to search, for the locale of the machine running the instance.
Message	System-generated description of the occurrence.
Level	Type of message displayed. The levels are Debug, Error, Warning, and Information. A warning is an error that has been handled and recovered. An error is something that must be fixed.
Thread name	System-generated identifier of the thread that created the log file.
Max rows	Maximum number of records returned for a particular filter.

The instance creates compressed archives of system logs every 2 days and purges log archives after 21 days.

Important: When a node is retired, the node's log files are purged immediately, which means they aren't archived for an additional 21 days.

You can download log file archives and view them with **System Logs** > **Utilities** > **Node Log File Download**. Select a log archive from the list, and then click **Download log** under *Related Links* to open or save the archive.

Note: Log files are only available for the node you are currently logged into. To see the currently logged into node, navigate to **System Diagnostics** > **Stats**.

Use the new **Show Syslog Records** button on the Transaction and Active Transaction forms to view any System Log entries that were generated during the execution of the transaction. A transaction can have any number of syslog entries. The multiple syslog entries for all the transactions make it difficult to co-relate a transaction with their respective syslog entries. The **Show Syslog Records** UI action helps in co-relating the active and completed transactions to their respective syslog entries by building a URL to query the syslog table. Identifying the correct syslog entries for a particular transaction helps in debugging and addressing security concerns.

Enhanced logging security

Explore the **Attribution** field in the node log lines to identify the script or component that generated the log message. Transaction start lines include the new field to identify the type of request made.

Achieve the following using the new enhancements:

- Trace the source originator of each of the log lines
- In case the originator info is not available, print the Java class name and an attribution
- At the start of each transaction line, it contains the transaction ID and transaction type

Use the transaction ID of each log line to understand the information given at each log line. Once you identify the transaction type, you get the originator information of each log line. Both the transaction type and originator information of each log line together gives you the required source info of each node log line.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note: SYS_UI_MACRO and SERVICE_PORTAL_WIDGET script types in attribution are not reported.

Transaction types

The following is the list of transaction types:

- List
- Form
- XMLHttp
- Report
- SOAP
- Export
- Scheduler
- TextSearch
- Other
- REST
- JSON
- AMB
- Archive
- Batch REST
- Instance Scan

System properties

The following are the system properties required for the feature:

- Glide.log.append.attribution: This property is enabled by default. It turns on/off the attribution information of each node line
- Glide.db.log.append.classname.attribution: This property is enabled by default. It turns on/off logging java class name attribution

Avoid log tampering

Configure system log table protection rules to limit the scope of modification and deletion of application log records. The rules enable you to determine the logging of changes or attempts to changes in these tables.

If you are a security_admin, activate the Protected Tables plugin (com.glide.protected_tables) that allows the platform to restrict update, insert and delete operations on the following system log tables:

- syslog
- syslog_transaction
- sys_outbound_http_log
- sysevent
- sys_audit
- sys_push_notification

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- syslog_app_scope
- protected_table_configuration (config not modifiable)

Note: The com.glide.protected_tables plugin gives protection only to the system log tables mentioned above. Any attempt to update, insert or delete a record logs a message in the protected_table_log table.

See Installing and configuring the log protection plugin for more details.

You can specify one of the following log protection levels for each of the system log table.

- Block and log the attempt: Blocks any modification and logs the attempt
- Only block the attempt: Blocks any modification and doesn't log the attempt
- Only log the attempt: Doesn't block the modification but logs the attempt
- Don't block and don't log the attempt: Doesn't block the modification and doesn't log the attempt

Platform uses the log protection levels specified for each of the system log tables to block and/or log any attempts to modify a record after being initially created.

Note: If you are a security_admin, you have the ability to override the default log protection levels in each of the system log tables to adapt to the customizations on your instance.

If there have been any attempts to modify the system log tables, they are logged into the protected_table_log table.

Note: If the protection level is not specified for a table, any attempts of modification are not logged into the protected_table_log table.

In order to disable the plugin operations on tables in the Admin Panel, set the com.glide.security.protected_table.enabled property to false. See Create log protection property for more information.

Configuring the log protection plugin

Configure the protection rules for each table and operation to complete the configuration of the log protection plugin.

Before you begin

Role required: security_admin

Procedure

1. Navigate to **All** > **Protected Tables** > **Log Protection**.
   The Admin Panel page is displayed.

   Note: Starting in the Utah release, the Protected Tables plugin is installed by default, but disabled.

2. Elevate your role to security_admin in order to continue configuring the plugin.

   a. Select **System Administrator**.

   b. Select **Elevate role**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The Elevate role modal shows up.

c. Select the security_admin option to elevate your role and select **Update**.

3. Configure the protection rules for each table and operation. The protection rules apply to update, insert and delete. The protection levels can't be changed for some tables. The syslog and syslog_app_scope tables have fixed values for update and delete protections. The protected_table_configuration table has fixed protection values for all three operations.

   Note: For sysevent table, insert protections can't be set to block.

   If you had **Apply to Child Tables** turned on for syslog in the previous release, the child tables are added to Log Protection with the same protection rules as syslog upon upgrade to the Utah release. This only happens for syslog, not for any other tables.

4. Enable the feature by selecting the **Enable Log Protection** toggle.

   Note: You can disable this plugin only by changing the com.glide.security.protected_table.enabled property in the sys_properties table.

Create log protection property

Create a log protection property to avoid the risk of log tampering.

Before you begin

Role required: admin

Procedure

1. If the *com.glide.security.protected_table.enabled* property doesn't exist in the System Properties list, select **New**.
   The new system property form shows up.
2. On the form, fill in the details

Fields	Description
Name	Name of the property as com.glide.security.protected_table.enabled
Application	Application that has the property.
Description	Description of the property
Choices	
Type	Value type - true or false
Value	Actual value of the property
Ignore cache	Option to ignore the cache content
Private	Option to make the property private ○ Read roles ○ Write roles

3. Select **Submit** to create the property.

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Logging, auditing, and errors (instance security hardening)

Apply a logging and auditing strategy so that you can identify and act on suspicious activity in a timely manner.

To learn more about what can be logged in the instance, see System logs. Ensure that there is a schedule for monitoring system events such as logins and failed logins by using **System Logs** > **Events**.

Disabling SQL error messages (instance security hardening)

Use the *glide.db.loguser* property to disable SQL error messages from rendering in a browser.

More information

Attribute	Description
Property name	glide.db.loguser
Configuration type	System Properties (/sys_properties_list.do)
Configurable in Instance Security Center	No
Purpose	To disable SQL error messages from displaying within the browser.
Type	true|false
Recommended value	false
Functional impact	(Low) This remediation disables rendering of SQL error messages. There is no impact to any functionality.
Security risk	(Medium) No sensitive SQL information that could help an attacker should appear as a part of error message on a web page.

To learn more about adding or creating a system property, see Add a system property.

Granular admin roles for Logging tables

Granular admin roles replace broad admin access with targeted, feature-specific permissions. Use these roles to grant the administrative capabilities needed for specific tasks without assigning the admin role.

Granular admin roles for Logging tables

Role name	Feature	Plugin	Description
syslog_viewer	System Logs (Log Entry)	com.snc.system_security	Provides read access to Log Entry (syslog) records.
syslog_admin	System Logs (Log Entry)	com.snc.system_security	Provides create/write access to Log Entry (syslog) records. The previous admin role ACL bindings

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Granular admin roles for Logging tables (continued)

Role name	Feature	Plugin	Description
			on the syslog table are deleted and replaced with these new granular roles.
txn_part_metrics_viewer	Transaction Part Metrics Logs	com.glide.transaction_part_metrics_log	Provides read and report_view access to the syslog_transaction_part_metrics table.
txn_part_metrics_admin	Transaction Part Metrics Logs	com.glide.transaction_part_metrics_log	Provides create, write, and delete access to the syslog_transaction_part_metrics table. The previous admin role ACL bindings on this table are deleted and replaced with these new granular roles. New ACLs for all five operations (read, create, write, delete, report_view) are introduced, each gated by the appropriate new role.

Secrets Management

Secrets Management lets you control which applications and users can access sensitive credentials stored on your instance.

Important:

Secrets Management Enterprise has begun its End of Life process and has reached the End of Sale and End of Renewal milestones as of the Yokohama release. For support storing passwords with two-way encryption, see Password2 encryption with the Key Management Framework (KMF).

Use Secrets Management to restrict access to passwords and other sensitive credentials beyond standard role-based controls, such as when different teams or applications share an instance but shouldn't have access to each other's credentials, or when your organization's security policies require fine-grained control over who can decrypt specific secrets.

Secrets Management has two available versions. Secrets Management Core is included on the ServiceNow platform at no additional cost and Secrets Management Enterprise is a premium, subscription version of the product. For more information on the difference between these versions, see Exploring Secrets Management.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Explore  Learn the key features and business value of Secrets Management.	Analyze  Learn more about Secrets Management dashboard.
Configure  Plan your core configurations.	

Exploring Secrets Management

Use ServiceNow Secrets Management for granular management of access to your passwords to fit your business needs.

Important: Admins must have the role to see modules and records related to Secrets Management. For secrets management role information, see Secrets Management roles.

Select from Core and Enterprise versions of Secrets Management

Choose from Secrets Management Core and Secrets Management Enterprise depending on your business needs.

The Secrets Management Core plugin (com.glide.sm.core) is available by default. No installation is required on the instance to use this plugin. The Secrets Management Enterprise plugin is only available with a ServiceNow Vault v1, PROD18537 license. Contact Customer Support for assistance with the Secrets Management Enterprise plugin.

Secrets Management Core	Secrets Management Enterprise
Secrets Management Core is available by default to install on your instance at no additional cost. The plugin provides the ability to use secrets groups with criteria in non-custom tables provided in the ServiceNow platform that have been created by ServiceNow application engineering teams.	Secrets Management Enterprise includes additional functions to help admins create and manage secrets groups. Enterprise provides the following features in addition to the features listed in Core.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Secrets Management Core	Secrets Management Enterprise
	• Use granular access controls to create secrets groups based on any of these criteria: ○ Scope ○ Package ○ Table ○ Column ○ Record • Create client-accessible secrets that are encrypted using your own key which ServiceNow can't access. • Use the Secrets Management Dashboard to review the secret groups configured on your instance and learn about potential security issues. **Note:** Secrets Management Enterprise is a paid plugin that ServiceNow personnel must activate on your production instance.

Use secret groups to organize your secrets

Use Secrets Management to organize your secrets into groups. Then, apply access policies to those secrets at a group level.

Basic secret group

These groups apply to all secrets in a scope. These secrets are decrypted by a common cryptographic module and module access policies (MAPs).

Secret group with criteria

Secret groups with criteria function the same as a basic secret group, but further refine what is included using criteria. These criteria include:

- Application scope
- Package
- Table
- Secret column
- Filter record

Secret groups of either type can be made instance accessible or client accessible.

Instance-side secret groups

Instance-side secret groups contain secrets that can be decrypted by your instance.

Client-side secret groups

Client-side secrets groups use a public/private key pair so that secrets can only be decrypted by the client. When you create a client-accessible secrets group, you upload the public key to the instance and retain the private key on your MID

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Server. The instance uses the public key to encrypt your secrets, but they can only be decrypted using the private key.

Note: For more information on these group types, see About client-side Secrets Management.

Use secrets groups for more granular control

While Password2 is available on the ServiceNow platform, Secrets Management provides these additional features.

Granular access controls	**Password2** With Password2, admins can control access to an application scope but can't restrict access to elements within the scope. **Secrets Management** With Secrets Management, admins can restrict access based on criteria they define. Criteria types can be based on criteria such as package, table, or column.
Secure storage	For client-side secret groups, Secrets Management uses a new encryption scheme. In this encryption scheme, ServiceNow doesn't save the encryption key. For this reason, the security of your data doesn't depend on ServiceNow's security.

Apply module access policies to your groups

After you've grouped your secrets into a secret group, you can apply policies that determine how you can access them at a group level. Module access policies are the access control mechanisms that you apply to cryptographic modules to define instance-level controls, such as a validity time frame for the cryptographic key. For more information on module access policies, see Module access policy overview.

Tables installed with Secrets Management

Secrets Management adds or modifies these tables.

New tables	
[sn_sm_secret_group]	Stores secret groups
[sn_sm_secret_group_criteria]	Stores criteria secret groups
[sn_sm_secret]	Stores wrapped secrets
[sn_sm_identity_group]	Defines the identity group for mapping a group of identities to the public key
[sys_kmf_wrapped_module_key]	Stores the wrapped symmetric cryptographic keys
Modified Tables	
[sys_kmf_crypto_module]	Added cryptographic module type (identity cryptographic module or secret group cryptographic module)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

[sys_kmf_module_key]	• Stores conceptual secret encryption key (with no key material) • Stores the identity public key
[sys_kmf_crypto_caller_policy]	Added new module access policy type

Secrets Management use case examples

Help ensure secure ITOM Discovery

This infographic shows a simplified reference architecture of how ServiceNow IT Operations Management (ITOM) Discovery can be deployed by your organization. As shown in the infographic, multiple Windows and Linux servers connect to the Management, Instrumentation, and Discovery (MID) Server and several MID Server agents enable the discovery process to update the Configuration Management Database (CMDB). Every MID Server transaction requires a secure authentication, so managing the authentication credentials is critical from a security perspective.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Accelerating workflow connectivity with Integration Hub securely

Use ServiceNow's Integration Hub to connect to different systems using automated application programming interface (APIs). Each time Integration Hub connects to a system using an API, an authentication credential is required to establish connectivity. Management of a multitude of applications and APIs for connectivity is made easier by using a secrets management solution.

Secrets Management is a key part of ensuring your organization's cybersecurity. It covers all processes and tools related to the creation, storage, transmission, and management of digital credentials such as encryption keys, API tokens, and passwords. To manage secrets both securely and effectively, you can build a core secrets management policy that establishes standard rules and procedures for all phases of a secret's lifecycle.

About client-side Secrets Management

Learn how use Secrets Management to manage access to secrets and groups.

Terminology

Client-side secrets management provides a method for managing secrets without the use of proxies, and without giving ServiceNow access to your decrypted data. To understand this process, begin with the following encryption terms.

Term	Description
Symmetric encryption	Symmetric encryption uses a single same key both to encrypt and decrypt data. If data is encrypted with a symmetric key, this key is all that is needed to decrypt it.
Symmetric key	The symmetric key encrypts a secret, turning your clear text password into unreadable cyphertext.
Asymmetric encryption	Asymmetric Encryption uses two keys, one to encrypt and the other to decrypt.
Public key	The public key is one half of the asymmetric key pair. This key is stored on your instance, which uses the key to encrypt a symmetric key. This encrypted symmetric key can only be decrypted when paired with the private key.
Private key	The private key is one half of the asymmetric key pair. This key is stored in a keystore on your MID Server. ServiceNow has no access to this key. Combined with the public key, the asymmetric key pair is used to decrypt your secrets.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Client-side encryption process

A symmetric key encrypts a credential (in this case, an admin password), changing it from readable cleartext into encrypted cyphertext.	
The symmetric key (represented in green) can be applied to the credential to encrypt or decrypt it.	
At this point, asymmetric encryption begins using public (green) and private key (blue) keys.	
The public key encrypts the credential along with the symmetric key. The symmetric key is now protected, so it can't be used to decrypt the credential. Although the public key can perform this encryption, it can't be used alone to decrypt.	
After being encrypted with the public key, the private key is needed to decrypt the credential. Since the customer alone has this key, they're the only ones who may access the encrypted credential.	

Configuring client accessible secrets

Learn how to configure your instance to use client accessible secrets.

Use this example implementation to configure Secrets Management without using proxies, or giving ServiceNow access to your decrypted data.

For more detail on using client-side Secrets Management to manage access to passwords and groups, see About client-side Secrets Management.

These instructions assume you have a MID Server configured on your local network. For information on this process see MID Server.

Process overview

1. **Create encryption keys and certificate**

   Create encryption keys and a certificate using terminal commands on your local environment.

2. **Add your certificate to the ServiceNow Trusted Key Store**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Upload your key and certificate to the ServiceNow Trusted Key Store.

3. **Create a secret group with criteria**

   Create a group for your secrets. Secret groups are used to organize your secrets into groups. Using these groups enables you to apply access policies to those secrets at a group level. Then associate your secrets group to an identity group and add your MID Server to that identity group.

4. **Upload the public/private keypair to the MID Server**

   Upload your public/private keypair to your MID Server. This keypair enables the MID Server to handle authentication requests from your instance.

5. **Create credentials and test credential encryption**

   Create a credential to authenticate into a third-party system and test that ServiceNow can't access the credential.

6. **Configure Flow Designer to manage the integration**

   On your instance, use Workflow Studio to manage an integration between your local network and your instance.

7. **Test the end-to-end client-side encrypted secrets integration**

   Test your integration, and review the execution details to confirm your configuration is working.

Create encryption keys and certificate

Create encryption keys and a certificate using terminal commands on your local environment.

Before you begin

Role required: none

Procedure

1. In your local environment, open Terminal (on Mac or Linux), or Command Line (in Windows).
2. Using the terminal, use `cd` to move into the folder where you want to store your encryption keys.
3. Using the terminal, enter the following:

```
openssl req -newkey rsa:4096 -nodes -keyout sm_private_key.pem
 -x509 -days 365 -out sm_public_cert.pem
```

   Note: This example uses OpenSSL to generate keys and certificates. You may substitute other comparable tools based on your requirements.

   The command generates a private key and a public certificate (with the matching public key). A series of prompts for required information follows, starting with “Country Name.”

4. Fill in the prompts with the requested information.
   The following prompts appear.
   - Country Name
   - State of Province Name
   - Locality Name (for example, city)
   - Organization Name (for example, company)
   - Organizational Unit name (for example, section)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Common Name (for example, fully qualified host name)
- Email address

Work with your security team to verify that you enter the correct certificate information.

```
Country Name (2 letter code) []:US
State or Province Name (full name) []:CO
Locality Name (eg, city) []:Boulder
Organization Name (eg, company) []:ServiceNow
Organizational Unit Name (eg, section) []:Product Management
Common Name (eg, fully qualified host name) []:fake@servicenow.com
Email Address []:fake@servicenow.com
```

5. Check the folder you that chose in step 2 to verify that the private key and public certificate have been created.
   If you used the same file names as in the step 3 example, you should see the following files:
   - sm_private_key.pem
   - sm_public_cert.pem
6. In the same folder, use the following command:

   Important: The specific command to use depends on your operating system.

For Linux:	`cat sm_private_key.pem sm_public_cert.pem > sm_keypair_bundle.pem`
For Windows:	`sm_private_key.pem sm_public_cert.pem > sm_keypair_bundle.pem`

   This command bundles the private key and public certificate into a single file to load into your MID Server in later steps.

7. Check the folder again to verify that the new file containing your private key (sm_keypair_bundle.pem) and public certificate has been created.

Add your certificate to the ServiceNow Trusted Key Store

Upload your key and certificate to the ServiceNow Trusted Key Store.

Before you begin

Role required: admin

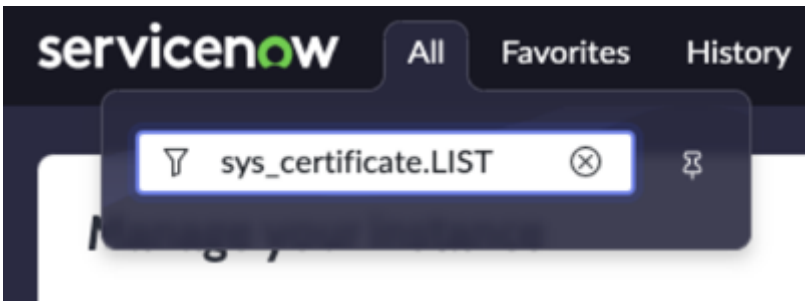
The public certificate that you created in this example is considered a “self-signed” certificate (meaning it didn't come from a trusted root authority). You must add the certificate to the ServiceNow Trusted Key Store for it to be used. When using a certificate that came from a Certificate Authority, you don't need to complete this step.

Procedure

1. In your local environment, open Terminal (on Mac or Linux), or Command Line (in Windows).
2. Using the terminal, use `cd` to move into the folder where you have created your encryption keys.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. In the terminal, enter the following command:



```
cat sm_public_cert.pem
```

You must view the contents of your public certificate to copy it into the trusted key store. This `cat` command displays the certificate.

4. Copy the certificate information to your clipboard.
Start with and include the `-----BEGIN CERTIFICATE-----` line and end with and include the `-----END CERTIFICATE-----` line.

5. On your ServiceNow instance, navigate to the **X.509 certificate** list by entering `sys_certificate.LIST` in the navigation filter.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

6. Select **New** to create a **X.509 Certificate** record.
7. In the form, fill in the following fields.

X.509 Certificate fields

Field	Value
Name	Name of the certificate. This name can be any name you choose.
Format	Select **PEM** **Note:** Privacy Enhanced Mail (PEM) files are a type of Public Key Infrastructure (PKI) file used for keys and certificates. The records you created in the previous steps are of this file type.
Type	Select **Trusted Store Cert**
Short Description	Description of the certificate. Enter a value that lets you know what this certificate is being used for.
PEM Certificate	Paste the certificate information that you copied in step 4.

8. Select **Submit** to save the record.

Create a secret group with criteria

Create a group for your secrets. Secret groups to organize your secrets into groups, and enable you to apply access policies to those secrets at a group level. Then associate your secrets group to an identity group, and add your MID Server to that identity group.

Before you begin

Role required: admin, sn_kmf.admin, sn_secrets.admin

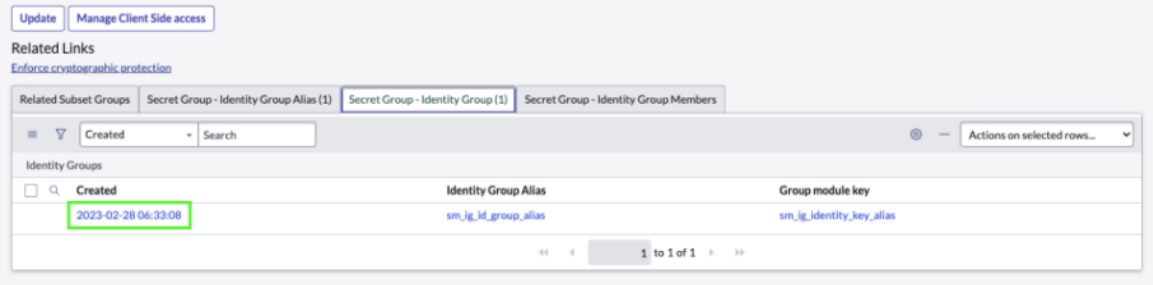
Procedure

1. Navigate to **All** > **Secrets Management** > **Secret Groups with Criteria**.
2. Select **New** to create a **Secret Group with Criteria** record.
3. In the form, fill in the following fields.

Secret Group with Criteria fields

Field	Value
Group name	Name of the secret group. This name can be any name you choose.
Secret type	Select **Client accessible**
Autogen module	Check the box

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Field	Value
Short description	Description of the secret group. Enter a value that indicates what this group is being used for.
Criterion type	Select **Target table**
Target table	Select **SSH Credentials [ssh_credentials]**

4. Select and hold (or right-click) the form header and select **Save** from the context menu to save the record.
5. Make sure that the **Active** check box isn't checked.
6. Select the **Manage client side access** button to create an identity group.
   An **Identity group alias** window displays.
7. Select the **New** button.
8. Select the reference icon ( ) next to the **Identity group alias** field.
9. In the **Group Alias Name** field, enter a value.
   This name can be any value you want.
10. If you chose a unique name in Step 9, select **Submit**.
11. Select the **Upload identity key** button.
    The **Import identity public key certificate** window displays.
12. In the **Identity key alias** field, enter a value.

    Important: This value can be anything you want, but it must be an exact match for what you insert into the MID Server in later steps.

13. Select **Import**
    The **Attachment** window displays.
14. Select **Choose file**.
15. Select the public certificate that you created in the earlier steps.
    This certificate should be the `sm_public_cert.pem` file.
16. Select the X icon to close the window.
17. Select **OK** to close the **Import identity public key certificate** window.
    A blue **Keys and certificates are successfully imported to the instance** banner displays confirming a successful import.
18. Select **Submit**.
    The **Identity groups** list displays.
19. Select the check box to the left of your identity group record in the list.
20. Select the **Associate secret group** button.
    You're returned to your **Secret Group with Criteria** record. The **Secret Group – Identity Group Alias**" and **Secret Group – Identity Group** related lists are visible. These related lists display the records that you created in the previous steps.
21. In the **Secret Group – Identity Group** related list, select the **Created** field for the record on that list.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

An **Identity group** record displays.

22. In the **Identity group members** related list, select the **New** button.
A **Identity group member** record displays.
23. In the **Member table** field, select **MID Server [ecc_agent]**.
24. Select the reference icon ( ) next to the **Identity group member record** field, and select your MID Server.

> **Note:** If you enable the **Include all records** check box, all MID Servers connected to your instance are added to the identity group.

25. Select **OK** to close the **Select the document** window.
26. Select **Submit**.
27. Navigate back to **All** > **Secrets Management** > **Secret Groups with Criteria**, and open the record you created in step 2.
28. Enable the **Active** field.
29. Select **Update** to save the record.

Upload the public/private keypair to the MID Server

Upload your public/private keypair to your MID Server. This keypair enables the MID Server to handle authentication requests from your instance.

Before you begin

Role required: none

Since ServiceNow lacks access to the private key, it can't pair it with the public key to decrypt the symmetric key and then decrypt the credential. If the MID Server tries to use this encrypted credential, it's unable to decrypt the credential for authentication without access to the private key.

In these steps, you upload the private key to the MID Server to complete the Public/Private keychain. This upload grants the MID Server access without giving ServiceNow access.

To grant the MID Server access to the private key, you must construct a command to be run as administrator in Powershell. In this example, the command is for the Azure Windows virtual machine.

> **Important:**
>
> Ensure that the system you perform these steps on has access to both the MID Server and the keypair file.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. In your local environment, locate the folder where you created your key pair in the Create encryption keys and certificate steps.
2. Find and copy the full path to the `manage-certificates.bat` file.

   Note: This file is located on your MID Server folder. Depending on where you've stored your MID Server folder, your path may look like this example:

   ```
   C:
   \Users\<your_user_account>\Documents\SM_Implementation\mid.
   utah-07-08-2022__patch4b01-31-2023_02-07-2023_1702.windows.
   x86-64\sm_ig_MIDS\bin\scripts\manage-certificates.bat
   ```

3. Create a text file and paste the path into the file.
4. In the text file, add the following after the path:
   `-a your_identity_key_alias`

   Replace `your_identity_key_alias` with the name of the identity key alias that you created when you uploaded your public certificate.
5. Find and copy the full path to your key pair file.

   Note: If you used the names in these steps that file is named `sm_keypair_bundle.pem`.
6. In your text file, add this path to the end of the line, adding a space between this path and the previous information.
   The text within your text file should look similar to this example:

   ```
   C:
   \Users\<your_user_account>\Documents\SM_Implementation\mid.utah
   -07-08-2022__patch4b01-31-2023_02-07-2023_1702.windows.x86-64\s
   m_ig_MIDS\bin\scripts\manage-certificates.bat -a
    your_identity_key_alias
    C:\Users\<your_user_account>\Desktop\sm_keypair_bundle.pem
   ```

   Note: In this example, the `sm_keypair_bundle.pem` file is on the desktop to make the path shorter.
7. Copy the entire text of your text file to the clipboard.
8. Find Powershell on your system, and choose the **Run as Administrator** option.
9. Paste the text from your text file into Powershell, and press Enter.
   If successful, you can see the following message:

   ```
   Installed certificate with alias: <your_identity_key_alias>
    into the MID keystore.
   ```

   Tip: If you don't see this message, ensure that your command has no errors, spaces, or unnecessary quotes. Ensure that the full path is typed correctly.
10. Restart your MID Server by navigating to your MID Server record, right-clicking the record, and selecting **Restart MID**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Restarting the MID Server synchronizes the uploaded key pair in the MID Keystore for use with operations. Wait for the MID Server to restart, with a status of **Up** and a validated value of **Yes** before continuing.

Create credentials and test credential encryption

Create a credential to authenticate into a third-party system.

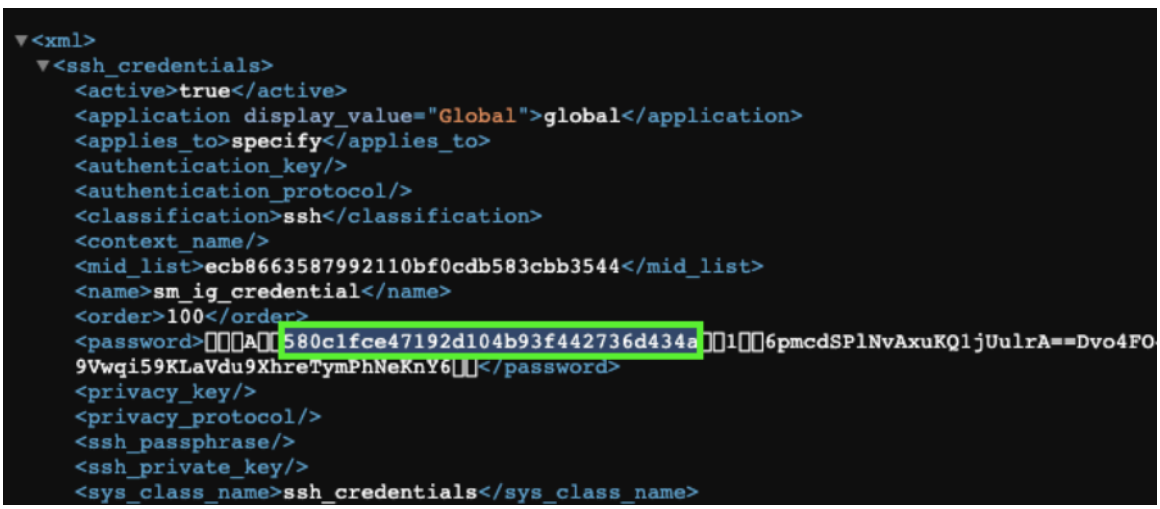
Before you begin

Role required: admin, KMF_admin, sn_secrets.secret_manager, and sn_kmf.cryptographic_manager

Important: The logged in user of the MID Server also is required to have the following roles: admin, KMF_admin, sn_secrets.secret_manager, and sn_kmf.cryptographic_manager.

Procedure

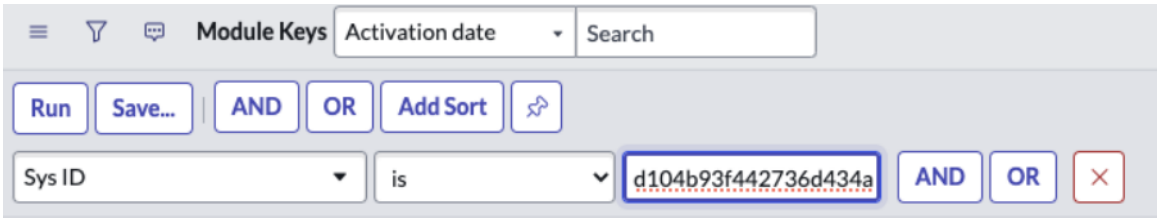
1. Navigate to the **SSH credentials** list by entering `ssh_credentials.list` in the navigation filter.
2. Select **New** to create an **SSH credential** record.
3. In the form, fill in the following fields.



SSH credential form

Field	Value
Name	Enter a name for your credentials record. This name can be any value you want.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Field	Value
Applies to	Select **Specific MID Servers**
MID Servers	Select your MID Server.
User name	Enter the user name.
Password	Enter the password related to the user in the **User name** field.

4. Select the lock icon ( ) next to the **Credential alias** field.
5. Select the reference icon ( ) to open the **Connection & credential aliases** list.
6. Select **New** to create a **Connection & credential alias** record.
7. Enter a name in the **Name** field.
8. Select **Credential** in the **Type** field.
9. Select **Submit**.
   You're returned to the **SSH Credentials** record. In the next steps, you test that the credential is encrypted.
10. Select and hold (or right-click) the form header and select **Show XML**.
11. Find the `<password>` XML tag within the XML.
12. Copy the sys_id within this `<password>` tag to your clipboard.
    The sys_id is a 32 character code representing the symmetric key that is being used to encrypt this credential. The encrypted password that you entered into the SSH Credentials table is to the right of the two sets of boxes on this same line.

13. Navigate to the **Module keys** list by entering `sys_kmf_module_key.list` in the navigation filter.
14. Filter the list for records where the **Sys ID** field matches the sys_id you copied in step 12, and select **Run**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Your search should return a single **Module key** record. This record shows you that you have successfully created, and are using, a symmetric key.

15. Navigate to the **Wrapped module keys** list by entering `sys_kmf_wrapped_module_key.list` in the navigation filter.
16. Filter the list for records where the **Crypto module** field matches the cryptographic module you created in the earlier steps, and select **Run**.
    Your search should return a single **Wrapped module key** record. From this list you can verify the following:
    - The **Wrapped key material** column shows that the symmetric key within the Crypto Module (that is being used to encrypt the SSH credential) is encrypted by the public key that you uploaded to the Identity Group.
    - The **Wrapped key sys id** field shows that it's the key (the Crypto Module symmetric key) that is being encrypted by the **Wrapping key sys id** (the Public Key uploaded to the Identity Group).

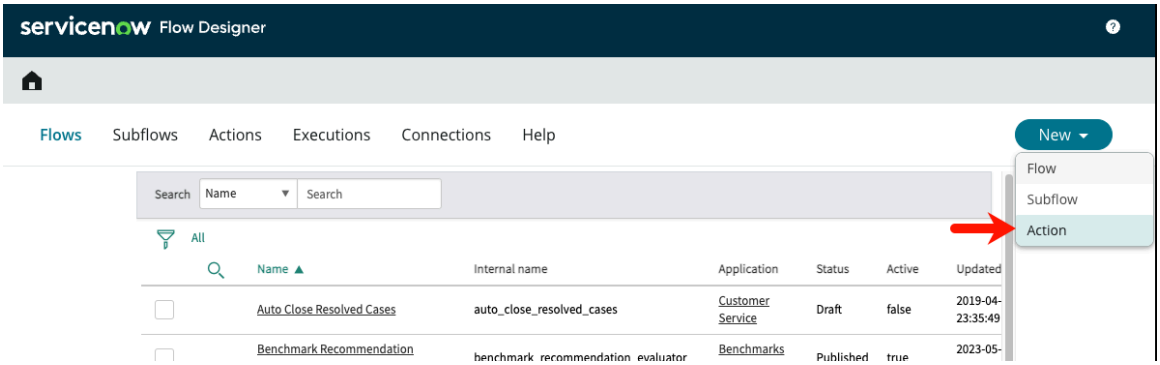
    If the preceding fields aren't on your list by default, you can add them to the list by selecting the **Personalize list** icon ( ).

    Note: Your instance executes a clean-up job every 10 minutes, which removes orphaned keys and helps prevent unassociated key proliferation after you update your credentials.

Configure Flow Designer to manage the integration

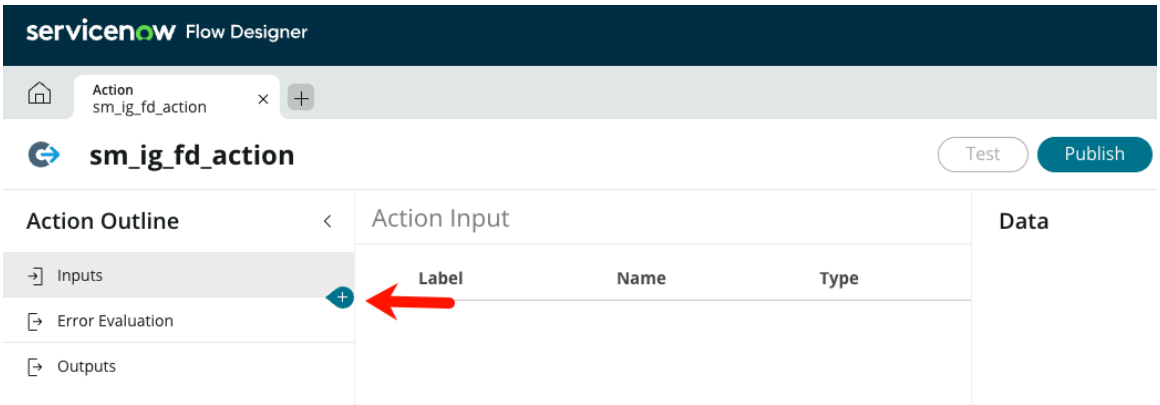
On your instance, use Workflow Studio to manage an integration between your local network and your instance.

Before you begin



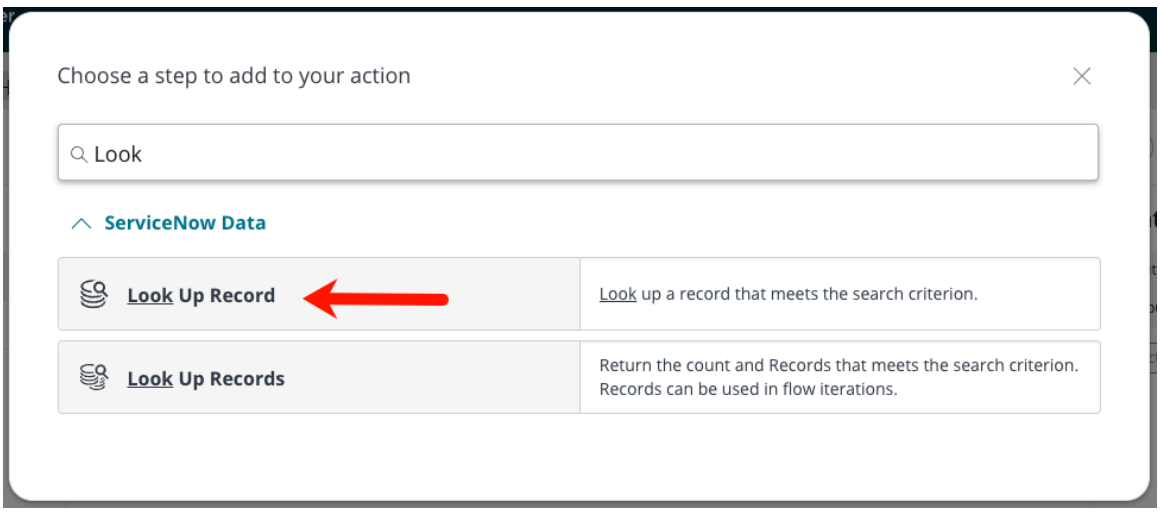
Role required: admin, KMF_admin, sn_secrets.secret_manager, and sn_kmf.cryptographic_manager

In these steps, you create a Workflow Studio workflow to create a text file on your local system.



Procedure

1. On your instance, navigate to **All** > **Process Automation** > **Flow Designer**.
2. Create an action in ServiceNow by selecting **New** and selecting **Action**.

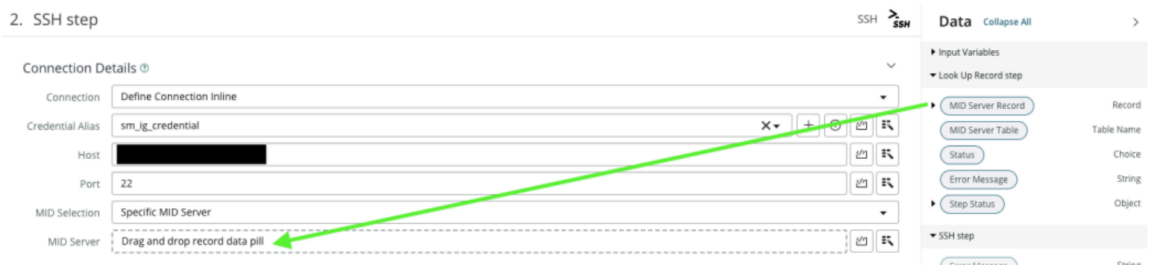


© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. Enter a name in the **Action name** field, and select **Submit**.
4. Create a step by selecting the plus sign between **Inputs** and **Error Evaluation** in the **Action Outline**.

5. In the **Choose a step to add to your action** window, select **Look Up Record**.

6. In the **Look Up Record step** section, select **MID Server [ecc_agent]** in the **Table** field.
7. Create another step by selecting the plus sign under your **Look Up Record step**.
8. In the **Choose a step to add to your action** window, select **SSH**.



Note: If you don't see the **SSH** option, you must activate the required plugin.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

9. In the **SSH Step** section, enter the following information:

Field	Value
Connection	Select **Define Connection Inline**
Credential Alias	Select the credential alias for the SSH credential that was created in earlier steps.
Host	Enter the IP address for the host that you're connecting to via SSH.
Port	Enter `22`.
MID Selection	Select **Specific MID Server**.

10. To fill the **MID Server** field, drag the **MID Server Record** pill from the **Data** section into the field.

> **Warning:** When dragging the pill into the field, select the pill and not the black arrow next to the pill.

11. In the **SSH Configuration** section, enter the following value into the **Command** field.

```
/bin/date > sm_ig_text_file.txt
```

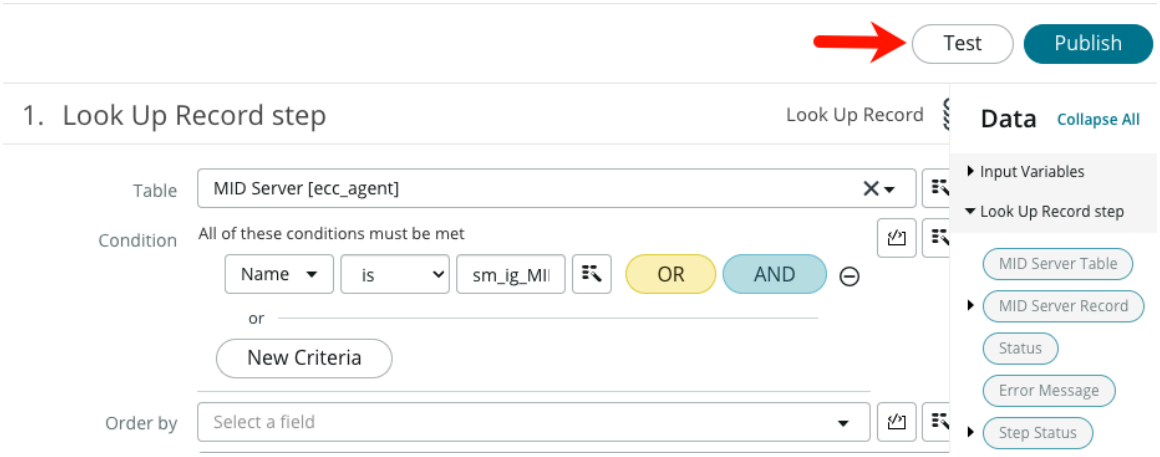
This command creates a text file in your local system using the decrypted secrets from the MID Server. The MID Server grants access to the ServiceNow instance (through Workflow Studio) without ever giving the ServiceNow instance access to the decrypted secret.

> **Tip:** The `/bin/date` command is inserting the current date/time into the created text file. This command demonstrates that the integration is happening in real time based on the current date/time versus when the text file was created.

12. Select the **Save** button to save the workflow.

Test the end-to-end client-side encrypted secrets integration

Test your integration, and review the execution details to confirm your configuration is working.



Before you begin

Role required: admin, KMF_admin, sn_secrets.secret_manager, and sn_kmf.cryptographic_manager

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. In Workflow Studio select the **Test** button in the top-right corner of the screen.

2. In the **Test Action** window, select **Run Test**.
3. Select **Your test has finished running. View the Action execution details.**
4. Refresh your screen until you see **Test Run – Completed** in the top-right side of the screen.
5. Select the **Steps** arrow at the bottom left of the screen.
6. Scroll down until you see a **Step Output Data** heading with the following success message:

```
{"Step Status";{"code";0,"message";"Success"}}
```

7. After seeing this message in Workflow Studio, verify that your text file has been created in your local system.

Test a Windows Management Instrumentation credential encrypted with Secrets Management

Verify that your Windows Management Instrumentation (WMI) credential is encrypted with Secrets Management and use an Integration Hub workflow to complete end-to-end testing.

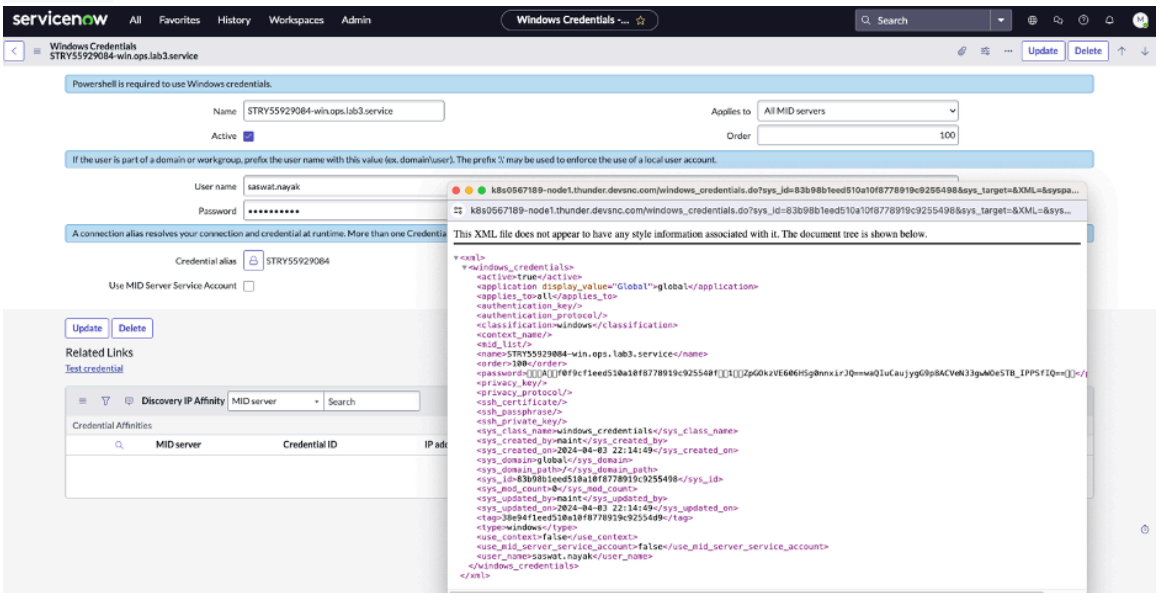
Before you begin

Role required: admin, KMF_admin, sn_secrets.secret_manager, and sn_kmf.cryptographic_manager

- Integration Hub Enterprise must be active on your instance. For details, see Request an Integration Hub plugin.
- You must have a configured secrets group on your instance. See steps 1 through 3 listed in Configuring client accessible secrets.
- You must have a configured credential encrypted with Secrets Management. See steps 1 through 9 listed in Create credentials and test credential encryption.

Procedure

1. Confirm that the desired MID Server is associated with the Secret Group.
   Open the Secret Group with Criteria [sn_sm_criteria_secret_group] record, and look for your MID Server in the **Secret Group – Identity Group Members** list. If your MID Server isn't associated with a group see Create a secret group with criteria.
2. Confirm that the credential is encrypted with Secrets Management.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Navigate to **All** > **IntegrationHub** > **Connections & Credentials** > **Credentials**.

b. Open your credential record.
Verify that you have a credential alias listed in the **Credential alias** field. If you have not created one already, see Create a Connection & Credential alias.

c. Select and hold (or right-click) the header of your credentials record, and select **Show XML** from the list.

d. In the XML view of the record, find the password and confirm that the value starts with □□□A□□.

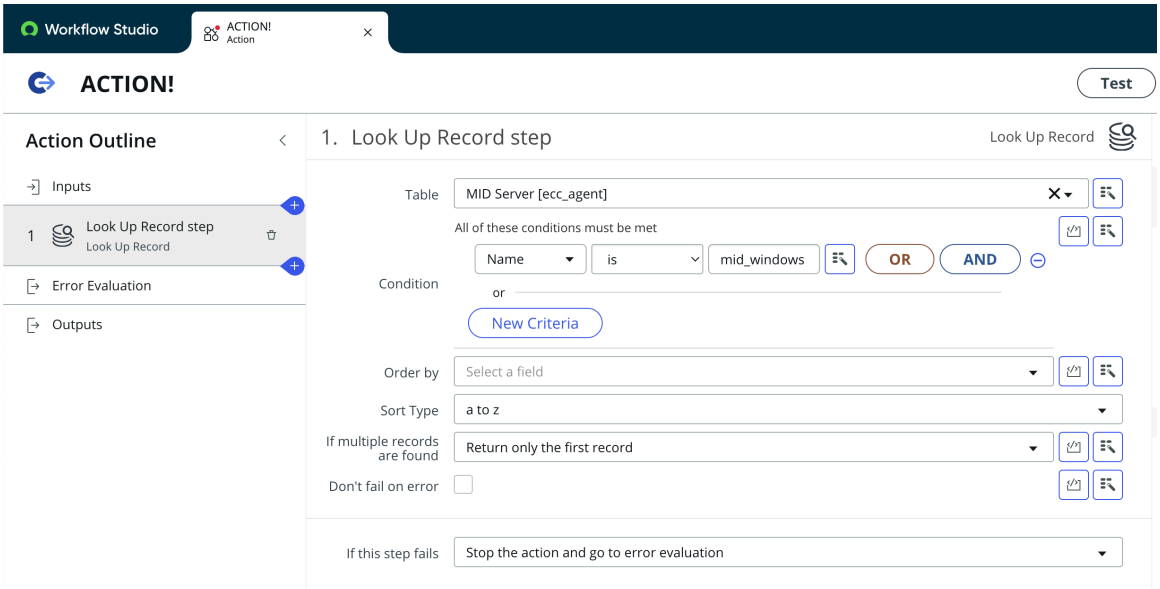
3. Create a testing workflow in Workflow Studio.

a. Navigate to **All** > **Process Automation** > **Workflow Studio**.

b. Select **New**, then select **Action** from the list.

c. Enter a name in the **Action name** field.
Leave the **Application** field set to Global.

d. Select the **Build action** button.



4. Configure a record lookup step in Workflow Studio.

a. In the **Action Outline**, select the plus button to add a new step.
Find and select the **Look Up Record** step type.

b. In the **Table** field, select **MID Server [ecc_agent]**.

c. For the condition, select **Name is**, followed by the name of your MID Server.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important: Make sure that the selected MID Server is the same as the one associated with the secret group.

5. Configure a record lookup step in Workflow Studio.

   a. In the **Action Outline**, select the plus button to add a new step below your Look Up Record step.
   Find and select the **PowerShell** step type.

   b. In the **PowerShell Step** form, fill in the fields as needed.

PowerShell step fields

Field	Value
Connection	Select **Define Connection Inline**
Credential Alias	Select your credential alias
Host	Enter the IP address of the target Windows server
Port	Enter 22 if it isn't already the default.
MID Selection	Select **Specific MID Server**
MID Server	Drag in the **MID Server Record** pill from the **Data** panel This data pill is visible in the **Data** panel on the right edge of the screen, under **Look Up Record step**.
Remoting Type	Select **Run on a MID Server or have your script establish a remote session**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

6. Create a script for your test action.

   a. In the **Script Type** field, select **Inline Script**.

   b. Use the following script, replacing the example path with the path from your test host.

```
Get-Date | Out-File -FilePath
 C:\Users\<path>\sm_ig_text_file.txt
```

   Note: You may also run your own script that suits your remote host configuration. It's important to confirm that a connection was established using the SM-encrypted value.

   c. Select the **Save** button to save your action.

7. Select the **Test** button to test your action.
8. Review the output logs for any error messages.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

9. Verify that a test file has been created on the host server in the file path you provided in the script.

Cloning and Secrets Management

Learn how to reconfigure secrets groups and client secrets groups after a clone.

After you clone an instance, your secrets groups and client secrets groups may require reconfiguration to operate as expected.

Secrets group origin	Behavior after a clone
Original instance secrets groups from the target instance	Works as expected after manually importing the missing cryptographic module. See Exporting and importing data via XML.
Original client secrets groups from target instance	Works as expected after manually importing the missing cryptographic module. See Exporting and importing data via XML.
Cloned instance secrets groups from source instance	Doesn't work unless manually set up
Cloned client secrets groups from source instance	Work if manually config sg/identity group/ alias/mid

Secrets Management dashboard

Use the Secrets Management dashboard to review the secret groups configured on your instance and learn about any security issues.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Secret Group Overview

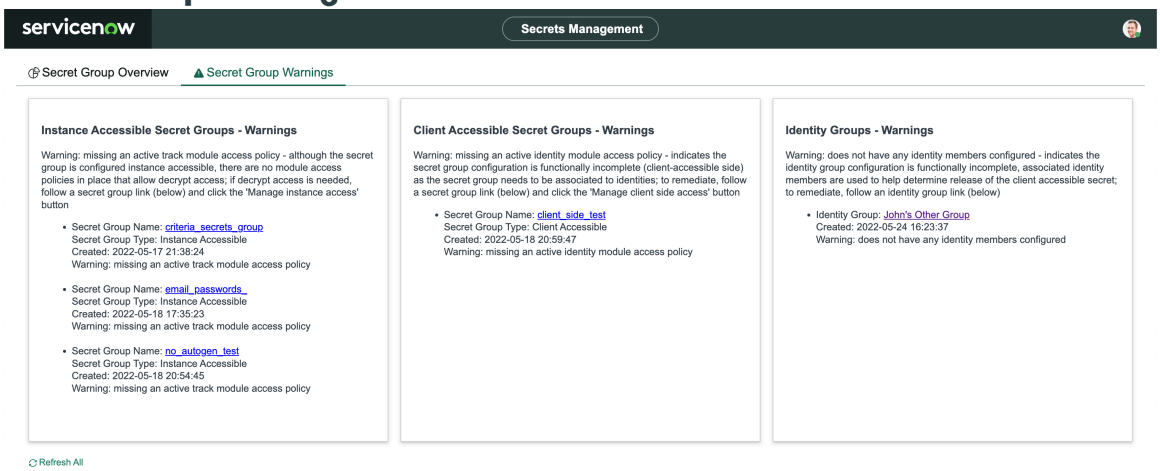
The **Secret Group Overview** tab displays information about your configured secret groups. Use this tab to see information about the secrets groups configured on your instance.

Secret Group by Type

Displays a pie chart showing secret groups installed on your instance, grouped by secret type (instance side of client side).

Secret Group by Criterion Type

Displays a pie chart showing secret groups with criteria configured on your instance by the type of criteria used.



Number of Inactive Secrets Groups

Displays a count of the inactive secret groups configured on your instance.

Number of Dedicated Secrets

Displays a count of secrets within basic secret groups.

Secret Group Warnings

The **Secret Group Warnings** tab displays warnings related to your secret groups and identity groups.

Instance Accessible Secret Groups- Warnings

This card displays warnings if there are secret groups with no active access policies in place. Select a secret group name to view that record.

Client Accessible Secret Groups- Warnings

This card displays warnings if there are client accessible secret groups that don't have an active identity module access policy (MAP). Select a secret group name to view that record.

Identity Groups- Warnings

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

This card displays warnings if there are identity groups that don't have group members configured. Select the identity group name to view the record.

Note: The Secrets Management Dashboard is a part of Secrets Management Enterprise. Secrets Management Enterprise is a Secrets Management Enterprise. Secrets Management ServiceNow's production instance.

Secrets Management roles

Secrets Management adds these roles.

Secrets administrator [sn_secrets.admin]

Assign non-admin secrets roles to other users. Secrets administrators have the same privileges as secrets manager and viewer.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

Important: Avoid granting an admin role when more specialized roles are available.

- A user must have both the admin and security_admin roles to be assigned the sn_secret.admin role.
- Avoid granting an admin role when more targeted roles are available.

Secrets Management [sn_secrets.secret_manager]

Grant this role to users who must be able to perform any of the following functions.

- View secret and secret group records
- View access history, and other usage activity info
- Create secret groups and filters
- Create secret providers
- Move secrets across secret groups
- Change secret group and secret provider settings

Contains Roles

List of roles contained within the role.

None.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

Important: Secrets managers can't see secrets in plain text.

Secrets viewer [sn_secrets.viewer]

Grant this role to users who must be able to view secret and secret group records.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

None.

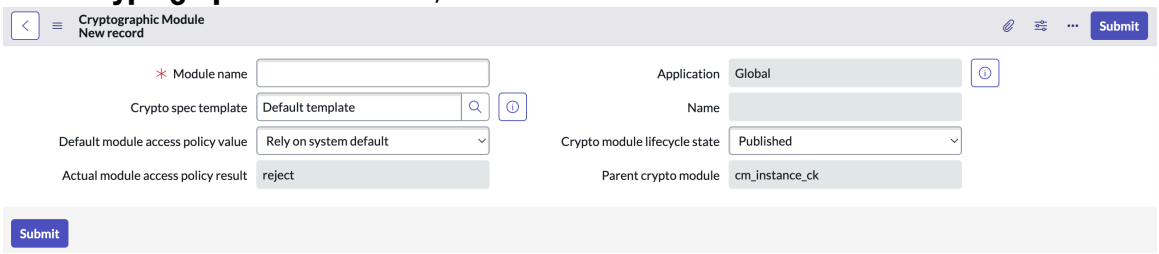
Create a secret group cryptographic module

Create a secret group cryptographic module to perform encryption and decryption.

Before you begin

Role required:

- admin
- sn_secrets.admin
- sn_secrets.secret_manager
- sn_kmf.cryptographic_manager
- sn_kmf.admin



Procedure

1. Navigate to **All** > **Secrets Management** > **Create Secret Group Crypto Module**.
2. Select the type of group crypto module you would like to create.

Cryptographic module type	Description
Create an instance accessible secret crypto module	Create instance accessible secrets that can be decrypted by your instance.
Create a client accessible secret crypto module	Create client accessible secrets that are encrypted using your own key, which ServiceNow can't access.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. In the **Cryptographic Module** form, fill in the fields.

Field	Description
Module name	Descriptive name for your module
Application	The application scope that contains your module. This field is automatically populated with the current module.
Crypto spec template	**Default Template** is selected by default.
Name	Name of the module. This name is automatically generated by based on the application and module name.
Default module access policy value	○ Rely on system default ○ Reject ○ Track
Crypto module lifecycle state	Whether the module is in a **Draft** or **Published** state.
Actual module access policy result	This field is for information purposes, and is read-only.
Parent crypto module	The parent cryptographic module, which is determined by the cryptographic module type you selected in the previous step. This field is read-only.

4. Select **Submit**.

Create a basic secret group

Create a basic secret group to group any secrets, regardless of their criteria.

Before you begin

Role required: admin

Basic secret groups can contain any secret you add to them, regardless of their table, scope, or application. After creating it, you manually add secrets to the group. To create a group specifically for all secrets that share a common attribute such as those, create a secret group with criteria using the instructions in Create a secret group with criteria.

Procedure

1. Navigate to **All** > **Secrets Management** > **Secret Groups**.
2. Select **New**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. For the **What type of Secret Group would you like to create?** option, select **Basic Secret Group**.
4. In the **Secret Group** form, fill in the fields.

Secret group fields

Field	Description
Group Name	Name for the group **Note:** Secret group names can only contain lowercase characters, numbers, and underscores(_)
Secret Type	Whether the group is **Instance accessible** or **Client accessible**.
Autogen Module	Generates a new cryptographic module for this secret group. This module encrypts and decrypts your data. This field is enabled by default.
Application	Scoped application for this record. This read-only field is automatically populated with the current scope.
Short Description	Description of the group
Crypto Module	Select the cryptographic module to use with this group. This module encrypts and decrypts your data. This field is only visible when **Autogen Module** isn't selected. For details on module access policies, see Module access policy overview **Note:** You can review the module access policies related to your secret group using the **Manage instance access** button.

5. Click **Submit**.

Note: When created, a secret group is inactive by default. Return to the group record and select **Active** to activate the group.

Create a secret group with criteria

Create a secret group with criteria to organize secrets entered in Password2 fields automatically when they share a common criteria, such as table, scope, or application.

Before you begin

Role required: admin, KMF_admin, sn_secrets.secret_manager, and sn_kmf.cryptographic_manager

Secrets within this type of secret group must all share common criteria. For groups without this restriction, consider creating a basic secret group. Learn about creating a basic secret group in Create a basic secret group.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Secrets Management** > **Secret Groups**.
2. Select **New**.
3. At the **What type of Secret Group would you like to create?** prompt, select **Secret Group with Criteria**.
4. In the **Secret Group** form, fill in the fields.

Secret group fields

Field	Description
Group Name	Name for the group **Note:** Secret group names can only contain lowercase characters, numbers, and underscores(_)
Secret Type	Whether the group is **Instance accessible** or **Client accessible.**
Autogen Module	Generates a new cryptographic module for this secret group. This module encrypts and decrypts your data. This field is enabled by default.
Application	Scoped application for this record. This read-only field is automatically populated with the current scope.
Short Description	Description of the group
Criterion Type	The criteria the secrets in this group shares. ○ Scope ○ Package ○ Target table ○ Secret column ○ Filter record
Crypto Module	Select the cryptographic module to use with this group. This module encrypts and decrypts your data. This field is only visible when **Autogen Module** isn't selected. For details on module access policies, see Module access policy overview **Note:** You can review the module access policies related to your secret group using the **Manage instance access** button.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

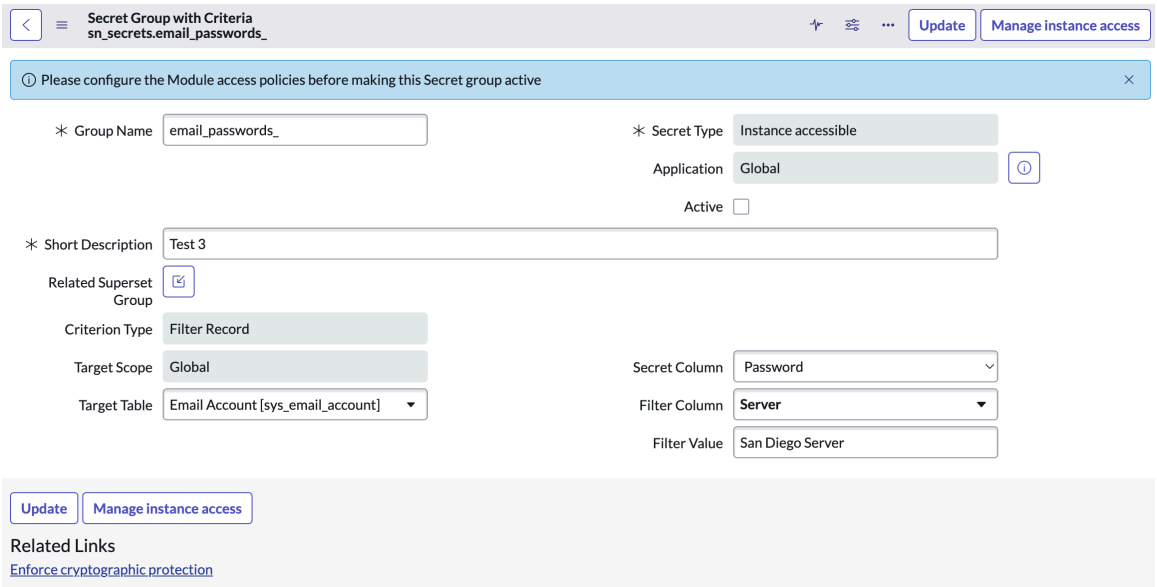
Note: Depending on your configuration, the **Crypto Module** might use an automatically selected value.

When the **Criterion Type** field is set to `Package`, and the **Autogen Module** field is selected:	The **Crypto Module** field is empty and read-only. An existing Password2 submodule is used. If a Password2 submodule isn't found, the instance level Glide Encrypter module is used.
When the **Criterion Type** field is set to `Package`, and the **Autogen Module** field is deselected: (The **Autogen Module** field can only be deselected by Enterprise users)	The **Crypto Module** field is editable, and admins can select a crypto module to use.

5. Select and hold (or right-click) the form header and select **Save**.

Note: When created, a secret group is inactive by default.

6. After saving the record, additional fields might appear based on how you've configured your group.



Additional secret group fields

Field	Description
Target Scope	Scope shared by the secrets to be assigned to this group. This field is only available when you select `Scope` in the **Criteria Type** field.
Target Package	Package shared by the secrets to be assigned to this group. This field is only available when you select `Package` in the **Criteria Type** field.
Target Table	Table shared by the secrets to be assigned to this group. This field is only available when you select `Table` or `Secret Column` in the **Criteria Type** field.
Application Scope	Application scope of the table selected in the **Target Table** field. This field is only visible when you select `Table`, `Filter Column`, or `Secret Column` in the **Criteria Type** field.
Secret Column	Table column that contains the Password2 secrets you include in this group. The fields available in this list are determined by the table selected in the **Target Table** field. **Note:** If there are no columns on the select table that contain secrets, this field only displays `– None --` as a selection.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Filter Column	The column on the table selected in **Target Table** you want to use as a filter. This field can't be a Password2 field.
Filter value	Value to filter by, based on the column selected in the **Filter Column** field.

Example: An instance accessible group containing all email account passwords for an email server

What to do next

After creating your group, any new records matching the criteria will be encrypted. To encrypt existing records using this group's cryptographic module, you must run a security job. For details, see Run Secrets Management security jobs.

Client-accessible groups need a customer-provided public key to encrypt your secrets. For steps on uploading this key, see Upload a public key for Secrets Management.

Upload a public key for Secrets Management

Upload a public key to encrypt your secrets in Secrets Management.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Secrets Management** > **Secret Groups** and open the secret group record.
2. In the record, select the **Manage Client Side Access** button.
   A new identity group record opens.
3. Select the **Upload Identity Key** button.
   A **Import identity public key certificate** window displays.
4. Enter an alias for your key in the **Identity Key alias** field.
5. Select the **Import** button, to upload the key from your local environment.
6. Select the **OK** button.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The **Group module key** field uses the identity key alias name.

7. Select **Submit** to save the identity group record.

Run Secrets Management security jobs

Schedule a Secrets Management job to perform encryption tasks on secrets fields on your instance.

Before you begin

Role required: sn_kmf.admin, security_admin, and sn_secrets.admin

To perform these steps, you must elevate to the security_admin role. For details on this process see, Elevate to a privileged role

Procedure

1. Navigate to **All** > **System Security** > **Security Jobs** > **Create New**.
2. At the **What type of Security Job would you like to create?** prompt, select **Secrets Management Job**.
3. On the form, fill in the fields.

Secrets Management Job form

Field	Description
Name	Name of the security job
State	The initial job state is New. After the job has been executed as scheduled, the state will update accordingly
Time window start	Start time for the job in 24-hour format. The job begins execution at the chosen time.
Time window end	End time for the job in 24-hour format. If the job isn't finished by this time, it continues during the next specified processing window until the job is complete.
Enforcement Level	Whether the job affects all tables, or a selection of specific tables or fields. Select from ○ All Tables ○ Specific Tables ○ Specific Fields ○ Specific Packages ⚠ **Warning:** Selecting the **All Tables** option may affect instance performance. Consider scheduling at non-peak hours.
Packages	The packages to include in this job. Encryption is applied to selected packages. This option displays only when the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Enforcement Level field is set to **Specific Packages**
Tables	The tables to include in this job. Encryption is applied to all applicable fields within the selected tables. This option displays only when **Enforcement Level** is set to **Specific Tables**
Fields	The tables to include in this job. Encryption is applied to all selected fields. This option displays only when **Enforcement Level** is set to **Specific Fields**
Job Mode	Select from **Password2 to Secrets Management** Encrypt all Password2 fields within your secrets groups using the cryptographic modules defined in each group's module access policy. **Secrets Management to Password2** Re-Encrypt data in your secrets groups using password2 encryption. For details on this encryption type see Password2 encryption with KMF. **Secret Group Enforcement** Queries all data that should match the group selected in the **Secret Group** field. If all the data found by the query is already in the group, the job makes no changes. If the query finds data that is not yet in the group, the job re-encrypts this data within the Secret Group. **Note:** If the data found in this query is already encrypted and your instances can't decrypt that data, it isn't encrypted and added to the secrets group.
Secret Group	Secret group containing the secrets to encrypt. This field is only available when **Secret Group** is selected in the **Job Mode** field.
Force rekeying data	Creates a new encryption key to replace an existing key. The data decrypts using the older key and re-encrypts using the new key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Summary	Displays information about the job progress. Summary also displays records that couldn't be encrypted by the job.

4. Select **Submit**.

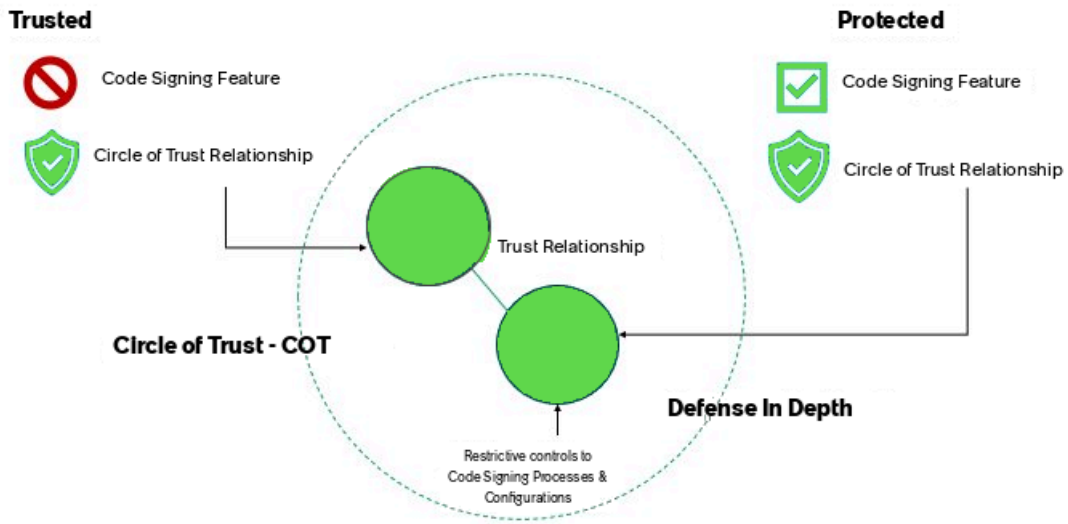
What to do next

The job queries all data that should match the selected secret group. If all the data found by the query is already in the group, the job makes no changes. If the query finds data that is not yet in the group, the job re-encrypts this data within the Secret Group. (If the instance can decrypt it, which may not be the case for client side-encrypted secrets).

Code Signing

Use Code Signing to create digital signatures that prevent unauthorized or tampered External Communication Channel (ECC) queue records from being processed by MID Servers. This cryptographic verification helps maintain the integrity of integrations between ServiceNow and external systems.

Code signing and Circle of Trust



The Circle of Trust (COT) is a prerequisite for Code Signing that creates secure communication between your trusted and protected instances to ensure that only authorized users can access the Code Signing feature.

Multiple security measures help to prevent malicious actors from disabling or misusing code signing in the case a protected instance is compromised. As part of the defense-in-depth strategy, the COT uses the following components:

- Controls that restrict even the most powerful administrator accounts are established in the protected instance to help protect Code Signing processes and configuration.
- Trusted instances are required to work together with protected instances to establish the Circle of Trust relationship. At least one trusted instance is required, but multiple trusted instances may be configured to collaborate with the protected instance.

Exploring Code Signing

Code Signing provides cryptographic verification to ensure that only authorized scripts can execute on MID Servers. Code Signing prevents unauthorized or tampered External Communication Channel (ECC) queue records from being processed by MID Servers, maintaining the integrity of integrations between ServiceNow and external systems.

Code Signing creates digital signatures for your data, which are later checked to confirm the authenticity and integrity of the data. Code Signing is a module licensed as a component of ServiceNow Vault.

Note: The Customer Service and Support team must grant access to Code Signing.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Code Signing declares the intent behind the operation being performed and validates whether the resource or record may be used for the intended purpose. To facilitate Code Signing, the Key Management Framework (KMF) uses digital certificates and industry standard asymmetric encryption for digital signatures.

Use Code Signing internally on the platform and infrastructure side. Code signing provides a way to sign the content of specific tables or of a subset of records in a given metadata table.

Code Signing uses a secure Circle of Trust (COT) between your trusted and protected instances to help ensure that only authorized, secure trusted instances can access the Code Signing feature.

Note: Code Signing is enabled on the protected instance and not on the trusted instance.

How Code Signing protects your environment

Without Code Signing, an attacker who gains access to ServiceNow records can modify SQL statements in a protected instance. When the MID Server processes this data source request, it would execute the malicious SQL commands, potentially compromising system integrity and security.

When you implement a Circle of Trust architecture with Code Signing, transfer of data to the MID Server follows the following verification process. This process helps verify that only authorized code originating from the trusted instance can execute on the MID Server. The process reduces potential attack vectors that could otherwise compromise your systems.

1. Digital signatures are applied to data sources created or updated within the trusted instance.
2. Use the Code signing process to transfer the signed data from the trusted instance to the protected instance.
3. The MID Server verifies the digital signature on all incoming requests, automatically rejecting any requests lacking valid signatures.
4. If the MID Server rejects a request, it logs this rejection and sends a notification to the protected instance.

Benefits of implementing Code Signing

Code Signing provides several key advantages:

Execution Control

Only cryptographically verified scripts can run on MID Servers

Tamper Detection

Any modifications to signed records are immediately identified and blocked.

Automated Protection

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The system handles security enforcement without requiring manual intervention.

Comprehensive Logging

All signature verification failures generate detailed audit records.

Change audit trail

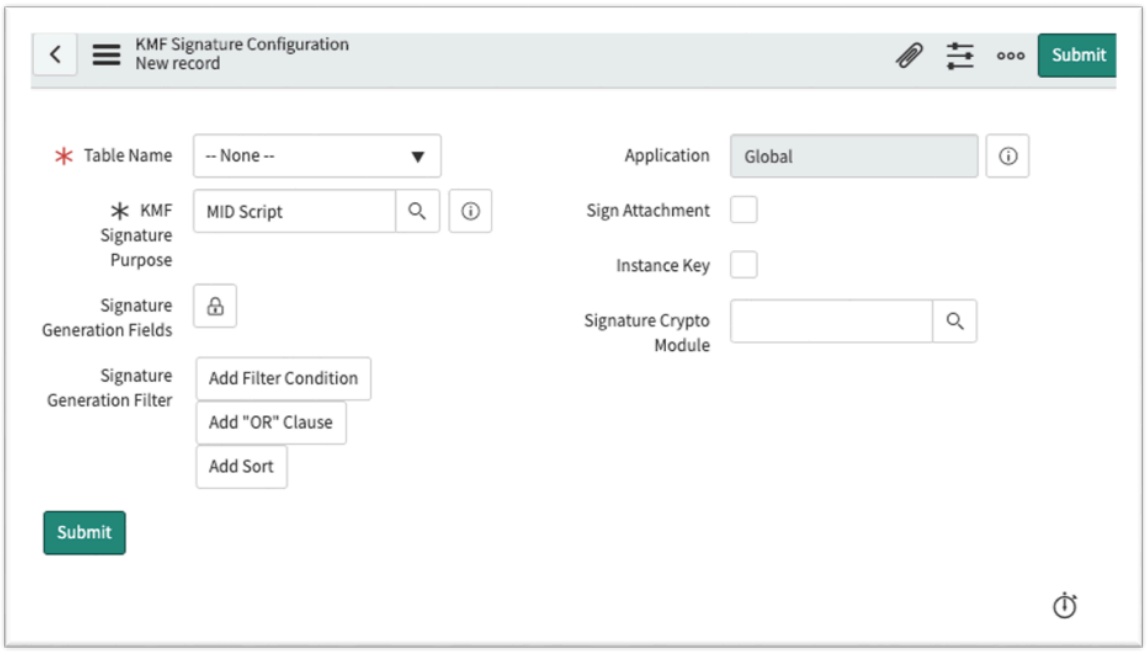
Code Signing records every create, update, and delete operation on a protected record, so you can identify who changed a record and when. For more information, see Code Signing change audit data.

Code Signing validation and jobs

All the metadata tables with valid configurations are signed at build time using the Code Signing metadata plugin (`com.glide.code_signing`). Installing this plugin automatically installs the Code Signing OOB App Signatures plugin (`com.glide.code_signing.oob_apps_signatures`) which contains build time signatures for all relevant records in the trued-up ServiceNow® Store application versions. If you choose to sign tables, admin users with the Security administrator role have access to Code Signing jobs:

- Sign update sets.
- Mass sign records.
- Mass sign attachments.

You can also generate signatures automatically when you commit application files to source control from a trusted instance. For more information, see Signature generation during source control commit.



Sign update set

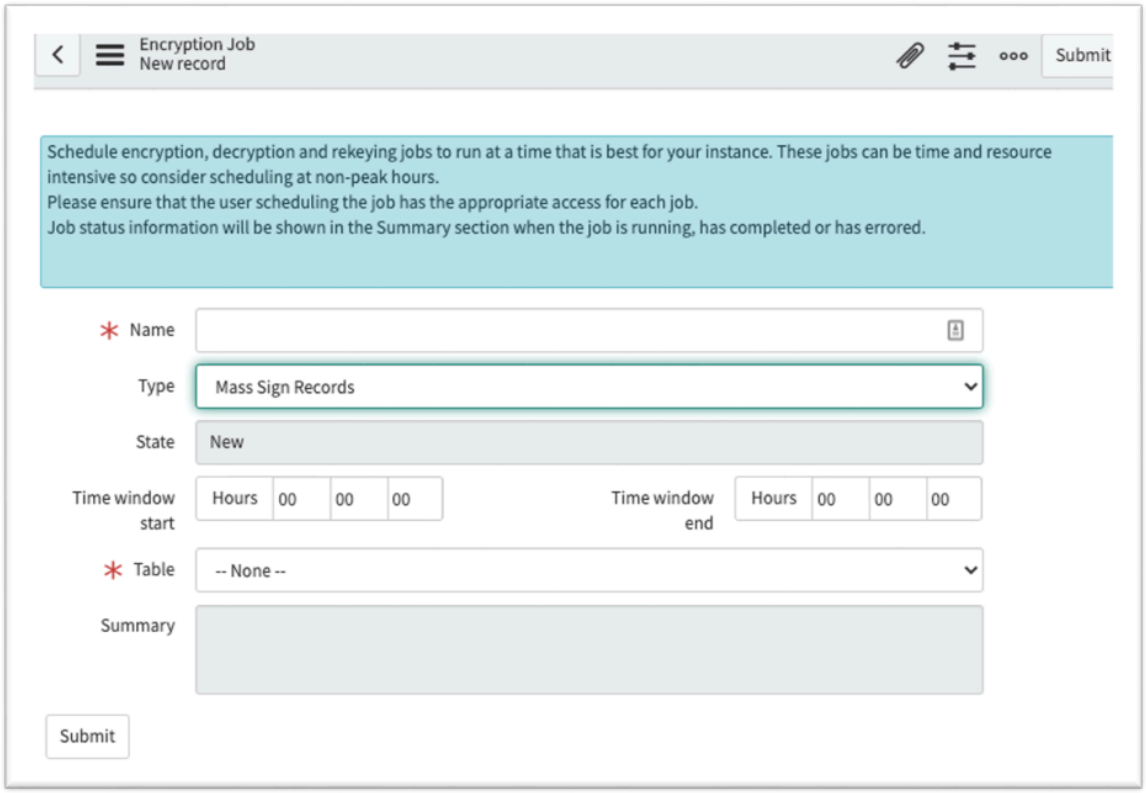
This job signs records that match a signature configuration in the update set. The job also adds all the new signature records and the verification certificates to the update set.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

KMF signature record for update set

Note: With the Australia release, script includes and business rule records are signed using the new "Wild Card Purpose". This replaces the previously empty purpose value. This change eliminates import warnings and manual intervention when handling large numbers of such records. You cannot create or update a signature configuration with the wild card purpose because it is already predefined. This value is reserved for script includes and business rules only, not for other tables. Attempts to use it elsewhere result in an error.

Mass sign records



This job signs all the records that match the signature configuration applied on a specific metadata table.

Mass sign attachments

This job signs all the attachment records that are attached to a table that matches a specified signature configuration.

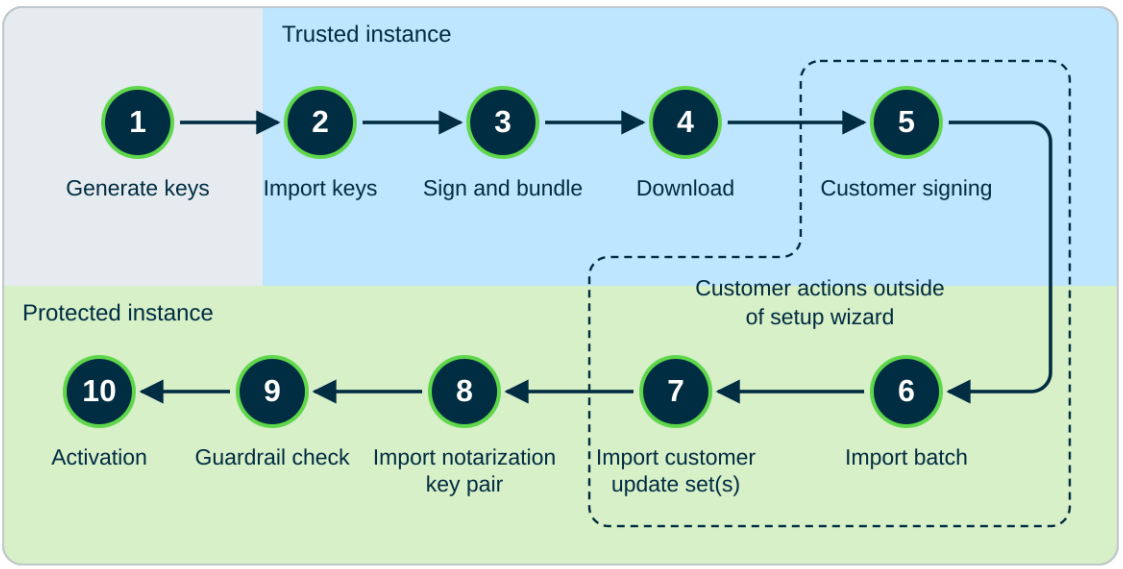
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Code signing job to mass sign records

Configuring Code Signing

Activate and configure Code Signing to verify the authenticity and integrity of your data.

Steps to turn on code signing and validation

Code Signing Enterprise requires an initial trust relationship between trusted and protected instances that helps to prevent any unauthorized user with any authorization level from accessing unapproved activities.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Refer to each topic to complete the configuration steps to establish the Circle of Trust with Code Signing Enterprise:

Assign the Code Signing Administrator Role

Assign the Code Signing Administrator role to a user to access the Code Signing configuration experience.

Configure Code Signing Enterprise on your trusted instance

Turn on Code Signing on your trusted instance.

Upload your Code Signing configuration file to your protected instance

Upload the configuration file generated on your trusted instance.

Configure Code Signing Enterprise on your protected instance

Turn on and configure Code Signing on your protected instance.

Turn on certificate validation

Turn on certificate validation on your instance.

Turn off Code Signing

Disable code signing on your protected instance.

Note: This optional step isn't part of the initial configuration for Code Signing

Assign the Code Signing Administrator Role

Assign the Code Signing Administrator role to a user to access the Code Signing configuration experience.

Before you begin

Roles required:

- admin
- security_admin

Important: The user that is assigned the Code Signing Administrator role must be in the Global scope.

Procedure

1. Select a trusted instance to use.
   The trusted instance is used to create jobs, sign records, and perform other necessary tasks before enabling signature validation on your protected Instance.
2. Navigate to **All** > **Code Signing** > **Administration** > **Role Administration**.
3. Grant a user the Code Signing Administrator role by moving a user from the **Available Users** list to the **Selected User(s)** list.
4. Select **Save**.

Important: The user assigned to the role must log out and lot in again to perform Code Signing tasks.

Result

The selected user has the Code Signing Admin role. A user with this role can access the Code Signing configuration experience, and assign other Code Signing roles to users.

To learn more about Code Signing roles, see Roles installed with Code Signing.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Configure Code Signing Enterprise on your trusted instance

Turn on and configure Code Signing on your trusted instance.

Before you begin

Roles required:

- admin
- security_admin
- codesigning_admin

> **Note:** The codesigning_admin role can be assigned using the process detailed in Assign the Code Signing Administrator Role.

- sn_kmf.cryptographic_manager

You must have at least one cryptographic key pair and certificate (p12 file extension) for customer signing and Circle of Trust (COT) administration. For improved security, consider using separate cryptographic key pairs for customer signing and COT administration.

> **Warning:** After completing this process, you will have downloaded a configuration file that must be installed on your protected instance within an hour. Verify that you have time available after this process to upload the configuration file to your protected instance. For details on that process, see Upload your Code Signing configuration file to your protected instance.

Procedure

1. On your trusted instance, navigate to **All** > **Code Signing** > **Configuration** > **Guided Setup** to open the Code Signing configuration page.
2. In the **Instance type** field, select **trusted instance**.
3. Select the **Next** button.
4. In the **Action** field under **Select the action you'd like to accomplish**, select **Turn on Code Signing**.
5. Next to **Attachments** in the **Customer signing key pair and certificate** section select **+Add File** to upload a cryptographic key pair (p12 file extension) to use for customer signing.

   > **Tip:** If the **+Add File** option is not available, verify that you are in the Global scope, and that you have the sn_kmf.cryptographic_manager role.

6. In the **Password** field, enter the password for the uploaded key pair.
7. Select **Import**.
8. Select **Continue** to move to the next section.
9. Next to **Attachments** in the **COT administration key pair and certificate** section select **+Add File** to upload a cryptographic key pair (p12 file extension) to use for customer signing.
10. In the **Password** field, enter the password for the uploaded key pair.
11. Select **Import**.
12. Select **Continue** to move to the next section.
13. On the **Export Configuration** file page, select **Export** to create and download a configuration file used to turn on Code Signing on your protected instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The export process downloads an XML file to your local machine for use in the steps details in Configure Code Signing Enterprise on your protected instance.

Note: Code Signing enforces limits on large update sets to improve the user experience. The maximum size for an update set is 10,000 records.

Upload your Code Signing configuration file to your protected instance

Upload the configuration file generated on your trusted instance.

Before you begin

Roles required:

- admin
- security_admin
- codesigning_admin

Note: The codesigning_admin role can be assigned using the process detailed in Assign the Code Signing Administrator Role.

- sn_kmf.cryptographic_manager

You also need the configuration file generated in the steps detailed in Configure Code Signing Enterprise on your trusted instance.

Procedure

1. Navigate to **All** > **System Update Sets** > **Retrieved Update Sets**.
2. Select **Import Update Set from XML** at the bottom of the Retrieved **Update Sets** list.
3. Select **Choose File**, and select your configuration file (xml file extension).
4. Select **Upload**.
   You should see the **Codesigning configuration** update set in the **Retrieved Update Sets** list.
5. Select and open the **Codesigning configuration** update set.
6. Select **Preview Update Set Batch**.
   If any conflicts occur during the preview, resolve them by selecting **Accept remote update** or **Resolve known CS conflicts**.
7. After resolving any conflicts, select **Commit Update Set Batch**.

Configure Code Signing Enterprise on your protected instance

Turn on and configure Code Signing on your protected instance.

Before you begin

Roles required:

- admin
- security_admin
- codesigning_admin

Note: The codesigning_admin role can be assigned using the process detailed in Assign the Code Signing Administrator Role.

- sn_kmf.cryptographic_manager

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. On your PPI, navigate to **All** > **Code Signing** > **Configuration** > **Guided Setup** to open the Code Signing configuration page.
2. In the **Instance type** field, select **protected instance**.
3. Select the **Next** button.
4. Select the **Please confirm the Code Signing configuration update set was imported and committed** check box.
5. Select the **Next** button.
6. Wait for the certificate installation to complete.
   A blue alert message displays indicating that items from the configuration file are installing. The alert disappears in a few seconds when the installation finishes.
7. Next to **Attachments** in the **Runtime/notarization key pair and certificate** section select **+Add File** to upload a cryptographic key pair (p12 file extension) to use for runtime/notarization purposes.
   You can re-use a key pair from the trusted instance or upload a new one specifically for this use.

   Tip: If the **+Add File** option is not available, verify that you are in the Global scope, and that you have the sn_kmf.cryptographic_manager role.

8. In the **Password** field, enter the password for the uploaded key pair.
9. Select **Import**.
10. Select **Continue** to move to the next section.
11. Wait while your instance performs a guardrail check.
    This check scans your instance for any invalid or missing signatures, and might take some time to complete. Don't exit or refresh the page until the scan completes.

    This workflow identifies signatures that were generated with expired or inactive certificates and re-signs the affected records. To improve performance, the workflow now divides the process into multiple events and runs them in parallel.

12. If the scan finds invalid signatures, select **Download Report**.

    Selecting **Download Report** downloads a report (`scan_report.txt`) that you can use to investigate and fix the invalid signatures.

    After resolving errors, refresh the page to re-run the check.

13. If there are no errors, select **Complete setup**.
14. Wait for the configuration jobs to complete.
    Your instance runs one or more jobs to complete the configuration process. Don’t exit or refresh the page until the jobs have finished. When finished, you should see a **Code Signing configuration completed successfully** message.

Result

Signature validation is now being enforced on your production instance. You can verify successful completion by looking at your system properties. Look for the **com.snc.kmf.signature.validation.flag** property on the System Properties [sys_property] table, and verify that it has a value of **true**. Verify that the **com.snc.kmf.signature.validation.certificate_trust** property doesn’t have an empty value.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Turn on certificate validation

Protect your instance with certificate based validation.

Before you begin

Role required:

- codesigning_admin
- security_admin
- sn_kmf.cryptographic_manager

Procedure

1. On your trusted instance, navigate to **All** > **Code Signing** > **Configuration** > **Guided Setup** to open the Code Signing configuration page.
2. In the **Instance type** field, select **trusted instance**.
3. Select the **Next** button.
4. In the **Action** field under **Select the action you'd like to accomplish**, select **Turn on Cert Validation**.
5. Select the **Next** button.
6. Next to **Attachments** in the **Customer signing key pair and certificate** section select **+Add File** to upload a cryptographic key pair (p12 file extension) to use for customer signing.

   Tip: If the **+Add File** option is not available, verify that you are in the Global scope, and that you have the sn_kmf.cryptographic_manager role.

7. In the **Password** field, enter the password for the uploaded key pair.
8. Select **Import**.
9. Select **Continue** to move to the next section.
10. Next to **Attachments** in the **COT administration key pair and certificate** section select **+Add File** to upload a cryptographic key pair (p12 file extension) to use for customer signing.
11. In the **Password** field, enter the password for the uploaded key pair.
12. Select **Import**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

13. Select **Continue** to move to the next section.
14. In the **Perform trusted instance tasks** section, wait for all tasks to be completed.

    Your instance generates and executes these tasks automatically. If you used Code Signing prior to the Vancouver release, tasks are created and executed to update your signatures.

    In some cases, no tasks are needed. **No tasks needed** displays on this page.
15. Select **Continue** to move to the next section.
16. On the **Export Configuration** file page, select **Export** to create and download a configuration file used to turn on Code Signing on your protected instance.
    The export process downloads an XML file to your local machine for use in the steps detailed in Configure Code Signing Enterprise on your protected instance.
17. On your protected instance, navigate to **All** > **System Update Sets** > **Retrieved Update Sets**.
18. Select **Import Update Set from XML** at the bottom of the Retrieved **Update Sets** list.
19. Select **Choose File**, and select your configuration file (xml file extension).
20. Select **Upload**.
21. Return to the code signing configuration page at **All** > **Code Signing** > **Code Signing Configuration**.
22. Use the wizard to complete your configuration, selecting the options for completing certificate validation activation.

Quorum Controlled Certificate Revocation

The quorum-controlled certificate revocation for Code Signing certificates provides a secure mechanism for a Code Signing admin to revoke Code Signing certificates. The revocation process involves submitting a request that requires approval from multiple stakeholders. This workflow helps to prevent accidental or unauthorized revocations.

This topic provides the high-level process overview for securely revoking certificates between a trusted instance and a protected instance using a quorum-based approval workflow.

- Request creation and export (Trusted instance): Initiate a quorum certificate revocation by creating a request with the required configuration properties. Export the update set, which includes the revocation request and related data. See Export Revocation Request Configuration
- Import and approval (Protected instance): Import the update set into the protected instance. Approvers receive notifications and must complete the approval workflow before the certificate is deleted. See Import the revocation request configuration
- Optional MID Server restart: If enabled in the configuration, MID Servers on the protected instance are restarted after the certificate revocation. This forces immediate certificate resynchronization but can result in data loss for unprocessed or cached events. See Approve certificate revocation

Note:

Your *update set* expires after the time window defined by the `com.snc.kmf.signature.validity_window` property. If it expires, you can export a new signed update set from the trusted instance. This validity window applies to all update set operations, including export, import, and enabling Code Signing. This validity window is not related to the request time window that you specify when creating the request.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Export Revocation Request Configuration

Start the certificate revocation process by selecting the certificate that you want to revoke. Provide the required configuration properties. Export this transaction as part of an update set, which is imported into the protected instance for approval and execution.

Before you begin

Role required: sn_cse.codesigning_admin, sn_cse.quorum_requester, security_admin

Procedure

1. On your trusted instance, navigate to **All** > **Code Signing** > **Configuration** > **Guided Setup** and open the Code Signing configuration page.
2. In the **Instance type** field, select **trusted instance**.
3. Select the **Next** button.
4. In the **Action** field under **Select the action you'd like to accomplish**, select **Certificate Revocation**.
   The Certification Revocation Request page appears.
5. In the Select Certificate to Revoke page, select the certificate that you want to revoke and select **Initiate Revocation**.
6. Configure the approval requirements for certification revocation.

   a. In the Quorum Requirements menu, enter the appropriate information in the text fields.

   Quorum Requirements Properties

Property	Description
Minimum approvals	Minimum number of approvers required to approve the certificate revocation request.
Time window	Expiration time for the revocation request.
Approvers	Email address of the users who are authorized to approve the revocation request.

   b. In the **Request description** field, enter the reason for initiating the certificate revocation.

   c. Select **Save**.
   The Export configuration file menu appears.

   d. On the Export Configuration file page, select **Export** to create and download a configuration file used to run certificate revocation workflow on your protected instance.

Result

The export process downloads an XML file to your local machine for use in the steps detailed in Configure Code Signing Enterprise on your protected instance.

Import the revocation request configuration

Import the update set into the protected instance to initiate the certificate revocation process. Approvers receive email notifications and they should complete the approval workflow before

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

the certificate is revoked. The approval means that the revocations are confirmed, authorized, and traceable for security and compliance purposes.

Before you begin

Role required: sn_cse.codesigning_admin, sn_cse.quorum_requester, security_admin

Procedure

1. Log in to your protected instance and navigate to **All** > **System Update Sets** > **Retrieved Update Sets** > **Import XML**.
   The Import XML page appears.
2. Select **Choose file** and select the configuration XML file from your local system.
3. Select **Upload**.
4. Return to the code signing configuration page at **All** > **Code Signing** > **Code Signing Configuration**.

   a. Review the following configuration files in the **Customer Updates in Batch** tab.
      - Code Signing Configuration Property (`time_window`)
      - Code Signing Configuration Property (`approver_email_ids`)
      - Code Signing Configuration Property (`minimum_approvals`)
      - Code Signing Configuration Property(`restart_mid_servers`)
      - Code Signing Quorum Request (CSEQC`xxxxxxx`)
      - Code Signing Transaction (CSETRANS`xxxxxxx`)
      - KMF Signature Records

   b. Select **Batch Update Set Preview** > **Commit Update Set Batch**.

5. Return to the code signing configuration page at **All** > **Code Signing** > **Configuration** > **Guided Setup**.
6. In the **Instance type** field, select **Protected instance** and select **Next**.
   The **Start or continue your configuration** page appears.
7. Select the **Confirm that the Code Signing configuration update set was imported and committed.** check box and select **Next**.
   In the Quorum Control Configuration page, review the information that you entered and select **Trigger Quorum Approval**.
8. In the Protected instance, select **Certification Revocation Status** in the Trigger Quorum Approval page to review updates on the quorum control request approvals.
9. Select **Approver details** and review the status of the quorum requests.

Approve certificate revocation

Review and approve certificate revocation requests from the email approval notifications that are sent to your registered email address. Review the approval notification and select the **Click here to approve** or **Click here to reject** link to access the protected instance and act. You can also access the approval request and the code-signing quorum request directly from the email.

Before you begin

Role required: sn_cse.codesigning_admin, approver_user

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Access the protected instance by following the links provided in the notification email.
2. Review the transaction requests under the Approvals menu.
3. Approve the task by selecting **Approve**.
4. In the approval confirmation page, select **Yes** to access the specific code signing quorum request.
5. Review the Code Signing quorum request and add any additional notes in the **Comments** menu, if necessary.
6. Select **Update**.

Result

The Code Signing quorum request is approved. If you have enabled the MID Server restart while exporting the revocation request, the MID Server restarts for the request to be activated.

Turn off Code Signing

Disable code signing on your protected instance.

Before you begin

Role required: admin, codesigning_admin

Procedure

1. On your trusted instance, navigate to **All** > **Code Signing** > **Configuration** > **Guided Setup** to open the Code Signing configuration page.
2. In the **Instance type** field, select **trusted instance**.
3. Select the **Next** button.
4. In the **Action** field under **Select the action you'd like to accomplish**, select **Turn off Code Signing**.
5. In the **Export configuration file** panel, select **Export** to download the update set.
   The export process downloads an XML file to your local machine for use in the next steps.
6. Select **Done**.
7. Log in to your protected instance.
8. Upload your configuration files using the steps in Upload your Code Signing configuration file to your protected instance.
9. Navigate to **All** > **Code Signing** > **Configuration** > **Guided Setup** to open the Code Signing configuration page.
10. In the **Instance type** field, select **protected instance**.
11. Select the **Next** button.
12. Select the **Please confirm the Code Signing configuration update set was imported and committed** check box.
13. Select the **Next** button.
14. Wait for the certificate installation to complete.
    After completion, a **Code Signing configuration completed successfully** message displays.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Result

You can verify successful completion by looking at your system properties. Look for the **com.snc.kmf.signature.validation.flag** property on the System Properties [sys_property] table, and verify that it has a value of **false**.

Load required key pairs and certificates for Code Signing

Establish the relationship in a designated trusted instance using Code Signing. This first step loads two cryptographic keys into the trusted environment to establish a trusted source for updates to the production instance.

Before you begin

Roles required: security_admin and sn_kmf.cryptographic_manager

About this task

The first step in establishing the relationship is to establish the trust foundation in a designated trusted instance using Code Signing. To perform this task, you need the following.

- You must have two 4096-bit RSA public/private key pairs to load into Code Signing cryptographic modules:
  - One pair for the cm_code_signing cryptographic module
  - One pair for the cm_code_attest cryptographic module

  For more information on these keys, see Create Code Signing key pairs and certificates.

  > **Important:** These key pairs must be signed by a public certificate authority or signed by your organizations internal certificate authority. The certificate can't be self-signed.

- A Public Key Cryptography Standard #12 (.p12) file containing your leaf and intermediate certificates.

Procedure

1. Import your keys from the keystore.
   a. Navigate to **All** > **Key Management** > **Cryptographic Modules** > **All**.
   b. Find and open the cryptographic module named `cm_code_signing`.
   c. In the **Crypto Specifications** list, select the name of the crypto specification to open it.
   d. In the **Import key from keystore** screen, select **Import key**.
2. Repeat the first step to import the cryptographic module named `cm_code_attest`.
3. In the **Enter Keystore Password** field, enter the challenge password you created when generating your RSA certificate.

   > **Note:** The challenge password that you created is referred to here as the **keystore password**. In other parts of the process, this may be referred to as either a **import password** or **export password**. In all cases, this password is the same challenge password that you created in the previous steps.

4. Select the **Browse** button next to **Import Keystore/Certificate**.
5. Select a Public Key Cryptography Standard #12 (.p12) file containing your distribution certificate (mentioned in the before you begin section at the top of this doc).
6. Select **OK**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important: If you're using your own internal certificate authority, you must upload the internal certificate authority's intermediate certificates using the process in steps 5–6.

With a successful import of your key and certificate(s), a confirmation message is displayed.

You can validate that the key and certificates are present on your instance on the X.509 Certificates [sys_certificate] table. These records have a type of **Trust Store Cert**.

You can validate your key on the Cryptographic Modules [sys_kmf_crypto_module] table.

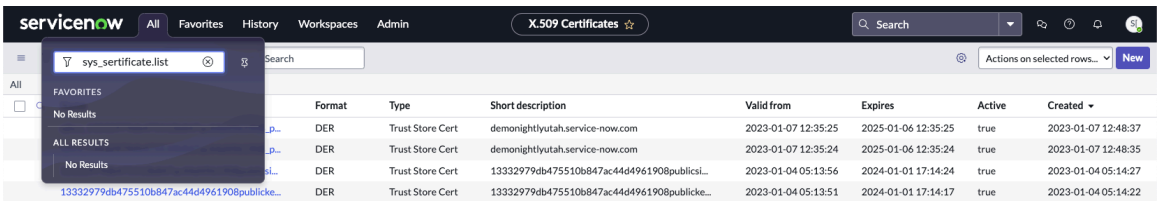
What to do next

Export the certificate to production. See Prepare Circle of Trust certificates for details.

Prepare Circle of Trust certificates

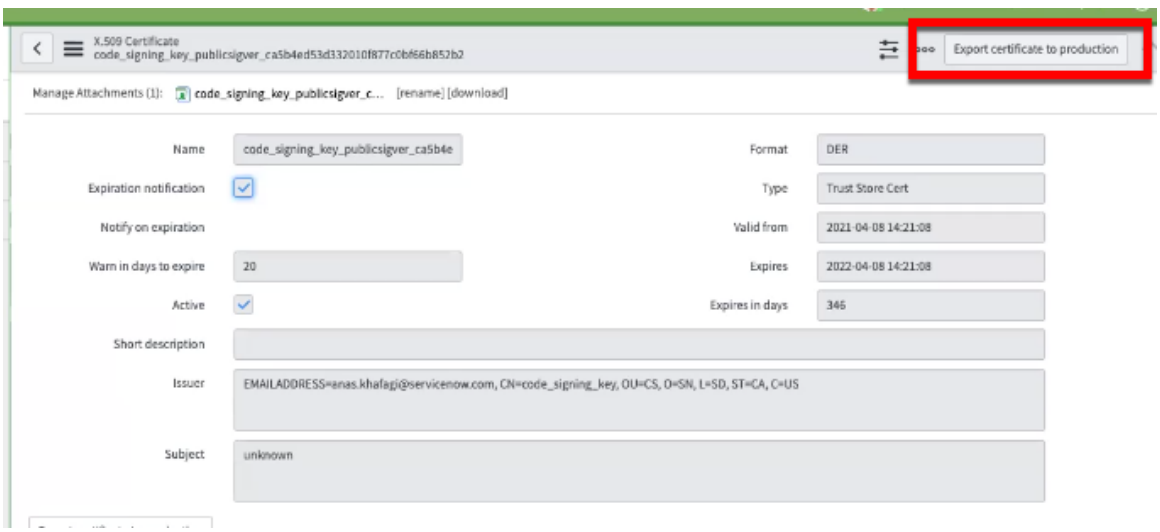
Create an update set in the trusted environment to export the trusted certificate to the production environment.

Before you begin



Roles required: admin, security_admin

Before you begin



Trusted instance

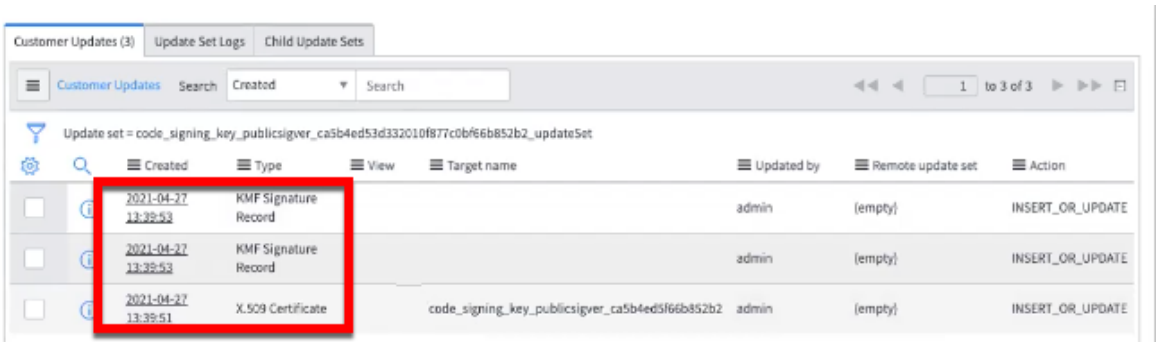
Procedure

1. In the trusted environment, navigate to **sys_certificate.list**.

2. Open the most recently created X.509 Certificate that was generated with the type **Trust Store Cert**.
   You may need to add the **Created** field to the list to find the most recent record. See Personal lists.
3. Select **Export certificate to production**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

A signature is created along with the certificate.



4. Navigate to **System Update Sets** > **Local Update Sets**.
5. Find and open the code signing update.

   This update starts with the text `code_signing_key_publicsigver`.

   A new code signing update set record has been created by the previous steps. To find this record, sort the list using the **Created by** field and look for records with in the **Name** field.

6. View the relevant Signature Records and the X.509 Certificate.

   The update set includes the attachment for the signature record along with the entry of the signature in the table and the certificate.

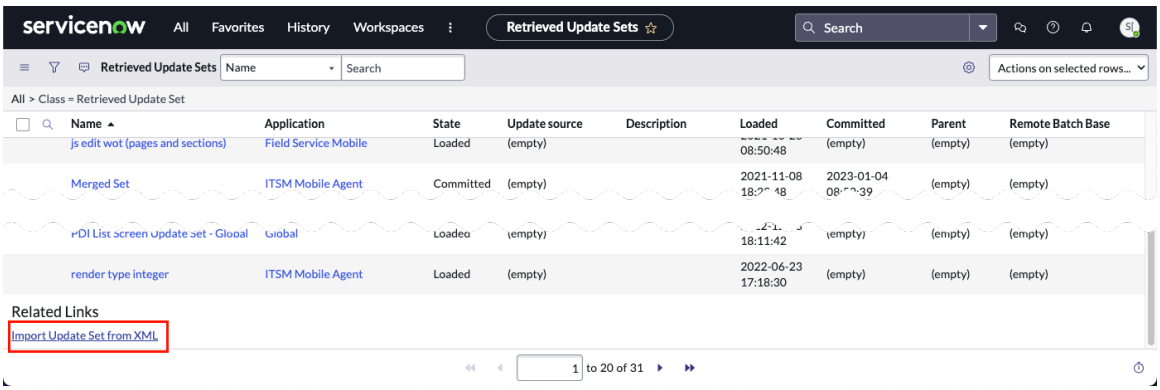
7. Select the **Export to XML** related link.

8. Retrieve the update set in production.
   See Retrieve an update set for details.

> **Important:** Repeat these steps for your second key pair. Remember that there's a key for both the cm_code_attest and cm_code_signing cryptographic modules.

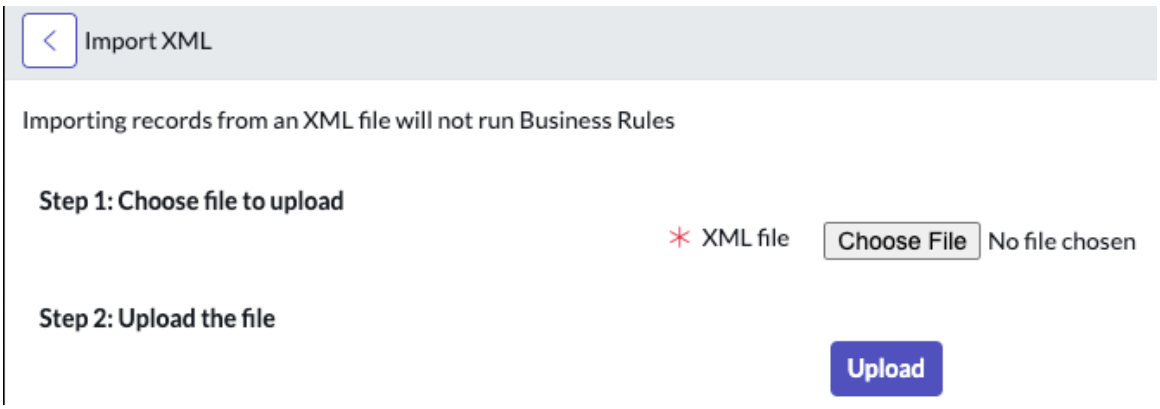
Import and install certificates for Circle of Trust

Retrieve the update set in production to establish the trust relationship between the two instances. The certificates that have been created to represent trust in the trusted instance must be accepted into the protected instance.



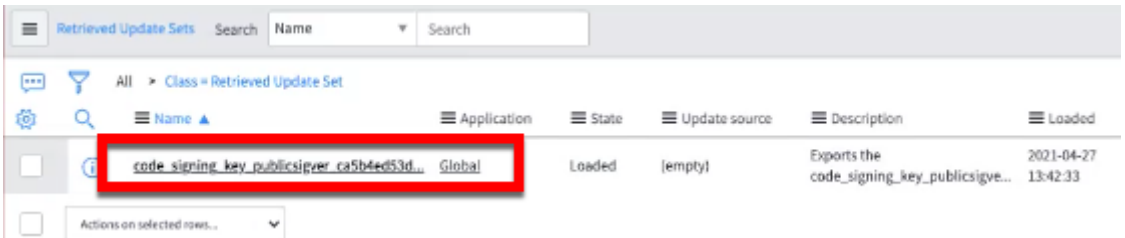
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin



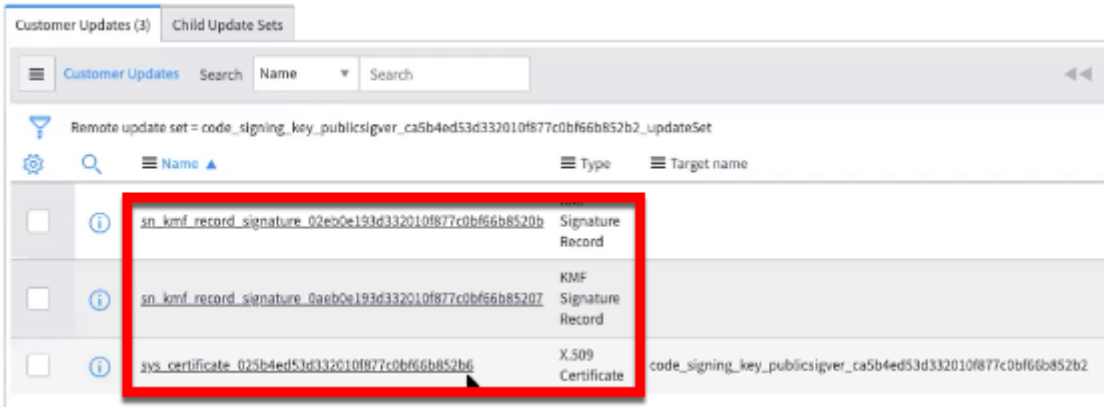
Roles required: admin, security_admin

Procedure

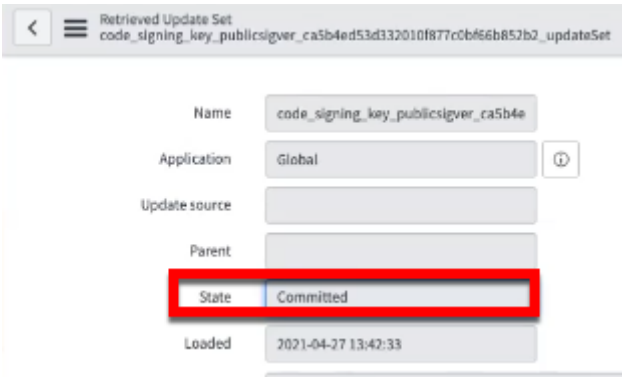


1. In the protected instance, navigate to **System Update Sets** > **Retrieved Update Sets**.
2. Select the **Import Update Set from XML** button on the bottom-left corner of the screen.

3. Select **Choose File** and browse to select the XML file that you exported in Prepare Circle of Trust certificates.



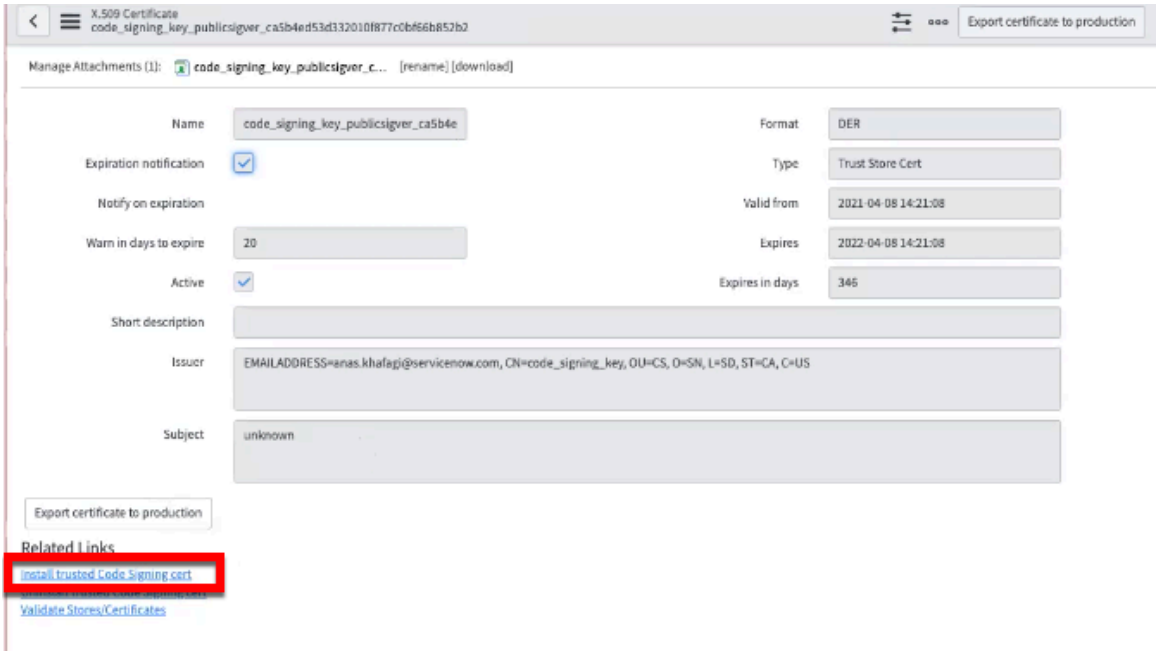
4. Select **Upload**.
   The Code Signing update set is added to the Retrieved Update Sets table.



> **Note:** If you don't see your update set, filter your list for records in the Loaded state, and sort the list by the **Loaded** field.

5. Open the update set record to verify that the Customer Updates table contains the following three records:
   - Two KMF Signature Records
   - X.509 Certificate

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



6. Select **Preview Update Set**.
7. Select **Commit Update Set**.

The Retrieved Update Set **State** updates to Committed.

8. In the navigator, enter `sn_kmf_record_signature.list` to open the **KMF Signature Records** list.
9. Locate the two KMF signature records.
These records are the most recently created records where the **KMF Signature Purpose** field has a value of `Circle of Trust`. You may need to add the **Created** field to your list, or filter for records created on the current date.
10. In the navigator, enter `sys_certificate.list` and open the record with a **Short description** value of *`code_signing_key`* and a **Type** value of `Trust Store Cert`.
11. Select **Install Trusted Code Signing cert**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The certificate type updates to *`Trusted CodeSigning Cert`*.

Important: Repeat these steps for your second certificate. Remember that there's a certificate for both the cm_code_attest and cm_code_signing cryptographic modules.

Result

The trust relationship is established between trusted and protected instances. You're ready to enable Code Signing. See Turn on Code Signing to complete the steps.

Turn on Code Signing

Turn on Code Signing in your trusted non-production instance to identify the trusted instances linking to your production instance.

Before you begin

Roles required: security_admin, and either sn_kmf.crypto_manager or sn_kmf.admin

As a customer administrator, you can access and install the Code Signing [com.glide.code_signing_enterprise] plugin from the ServiceNow Plugin portal. To learn more about the use cases of Code Signing, see Exploring Code Signing.

About this task

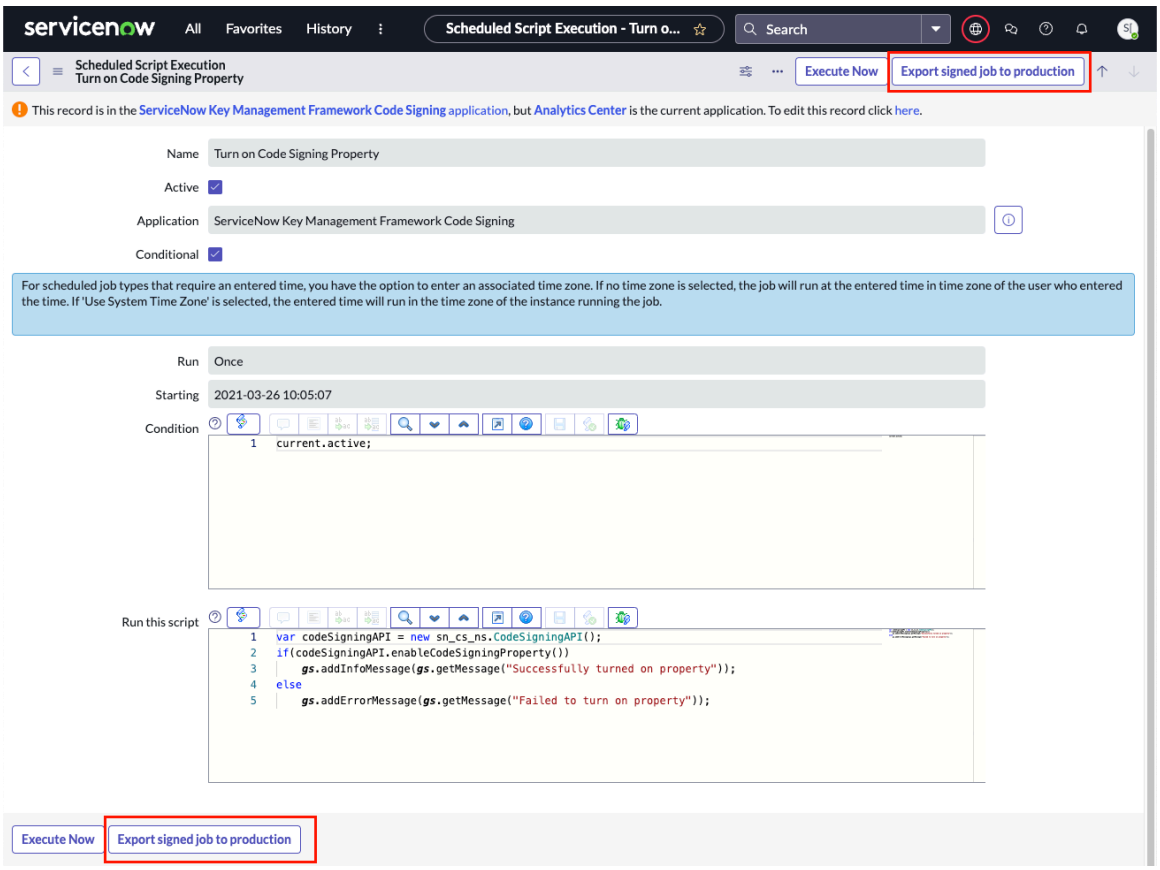
Code Signing jobs with signed update sets are used to turn the Code Signing feature on or off. There's no other method for this functionality. This process includes the following:

- Create two Code Signing jobs in the trusted instance, one to turn on Code Signing and one to turn off Code Signing.
  - The **Turn On** scheduled job starts the process of MID Server validation of signed code.
  - The **Turn Off** scheduled job stops the MID Server validation of signed code.

  By default, Code Signing applies to all MID servers. However, if you need to restrict Code Signing to a specific subset of MID servers, you can achieve this by using the ECC firewall.

  Note: When turning off Code Signing, the system property is marked to **false**, but the Code Signing trusted friends list is still available.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

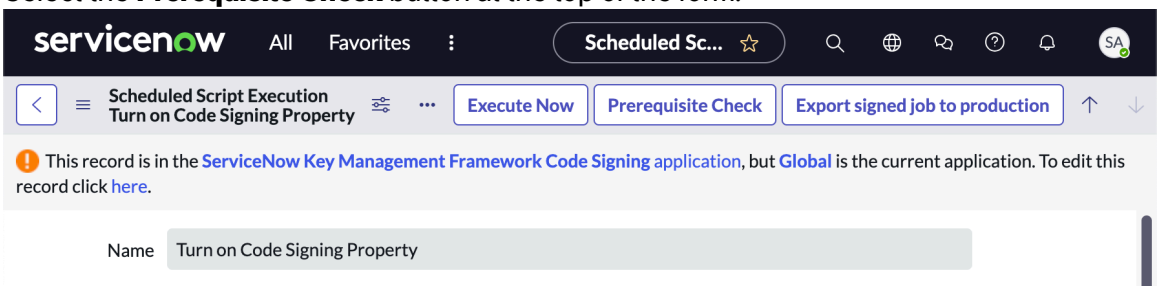


- Put the **Turn on Code Signing Property** job into an update set.
- Bring the job into production.
- Use the **Turn on Code Signing Property** job in production if the signature is verified to originate from a trusted instance.

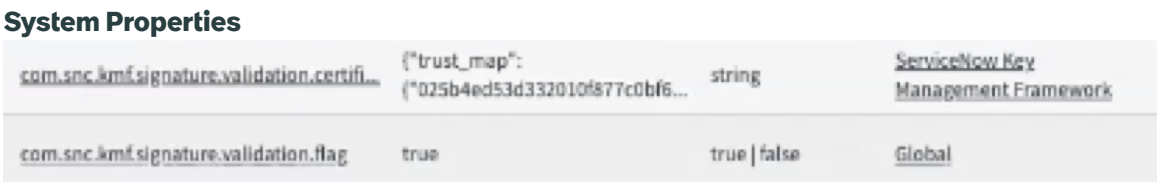
Procedure

1. In your trusted instance, navigate to **All** > **System Definition** > **Scheduled Jobs**.
2. Search for "*Turn" in the name field.
3. Select **Turn on Code Signing Property**.

The **Scheduled Script Execution** form load. This form contains information to enable the Code Signing property. The jobs create update sets that contain the jobs and validated signatures through the Code Signing process.



4. To execute the script immediately, sign the certificate, create the update set, and select **Export signed job to production**.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You can also configure the script to run on a designated schedule.

5. Navigate to **System Update Sets** > **Local Update Sets**.
6. Open each of the Code Signing property update sets and select **Export to XML**.
7. Log in to the production instance.
8. Navigate to **System Update Sets** > **Retrieved Update Sets**.
9. Select the **Import Update Set from XML** button, and select the Code Signing property update set.
10. Select **Choose File** and upload and commit the update sets.
11. Return to the scheduled jobs list by navigating to **All** > **System Definition** > **Scheduled Jobs**.
12. Open the **Turn on Code Signing Property** job record.
13. Select the **Prerequisite Check** button at the top of the form.

14. Select the **Execute Now** button after the prerequisite check is complete.
The **Turn on Code Signing Property** scheduled job starts the process of MID Server validation of signed code.
15. In the navigator, enter `sn_kmf_record_signature.list` to open the **KMF Signature Records** list, and filter for records where the **KMF Signature Purpose** is `Circle of Trust`. The trust relationship has moved the jobs over and when the jobs are used the signature verification process executes. If the jobs, signatures, and certificates are all part of the Circle of Trust, then Code Signing with Circle of Trust can be turned on.
16. In the navigator, enter `sys_properties.list` to open the system properties list.
17. Search for *`com_snc_kmf_signature.validation.flag`* and ensure that the value is set to **true**.
18. Verify that a new property *`com_snc_kmf_signature.validation.certificate`* is listed in the table.

Use the Circle of Trust job in production to verify the trust relationship. No direct job can be executed in production that attempts to sign code. See Configuring Code Signing for details on configuration options.

Create Code Signing key pairs and certificates

Create two key pairs to signed certificates to establish trust between your protected and trusted instances.

To establish trust between your instances, you must create a key pair and certificate for each of the `cm_code_attest` and `cm_code_signing` cryptographic modules.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Creating key pairs and certificates is done using a cryptographic tool installed on your local device, such as the OpenSSL tool. For more information on this tool, see https://www.openssl.org. If your organization uses other cryptographic tools, such as LibreSSL or GnuTLS, refer to the documentation for those products for similar steps.

Key pair specifications

The key pairs you create must meet these requirements.

Type	RSA
Key length	4096
Signing algorithm	RSASSA_PKCS1_V1_5_SHA_512

Certificate specifications

Certificates must be signed by a public certificate authority.

Specify custom rules in ECC firewall

Configure the External Communication Channel (ECC) firewall in your MID Server by specifying the custom rules to selectively allow or reject the incoming message and override the Code Signing configuration.

Security administrators can use the ECC firewall tags to override the Code Signing configuration and allow or reject specific operations on MID Server. These custom rules must be specified in the YAML file of the located at: `agent/boot-config.yaml`.

These tags are specific to a protocol. The configuration specified for the parent tag is applicable to the child tag. For example, if `Http` protocol is allowed, `rest` and `soap` protocols are also allowed. This table outlines the available parents and child tags.

Parent tag	Child tag
DNS	
HTTP	• REST • SOAP
DIRECTORY_SERVICES	LDAP
SNMP	
SSH	• SCP • SFTP
SYSLOG	
WINDOWS	• CIM • POWERSHELL

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Parent tag	Child tag
	• WMI • WINRM
JAVASCRIPT	
GROOVY	
VCS	GIT
DATABASES	JDBC
DATA_SOURCES	
INTEGRATION_HUB	
ITOM	• CLOUD_PROVISIONING_GOVERNANCE • DISCOVERY • EVENT_MANAGEMENT • HEALTH_LOG_ANALYTICS • SERVICE_MAPPING
ORCHESTRATION	

To configure the custom rules:

1. In the MID Server, identify the file `boot-config-sample.yaml`.
2. Rename the YAML file to `boot-config.yaml` and move the file to the location: `agent/boot-config.yaml`.
3. In the YAML file, specify the custom rules and save the changes. An example of the YAML file:

```
security:
  eccFirewall:
    mode: enforcing

        action: accept
      - tags: [soap]
        action: accept
      - tags: [jdbc]
        action: reject
```

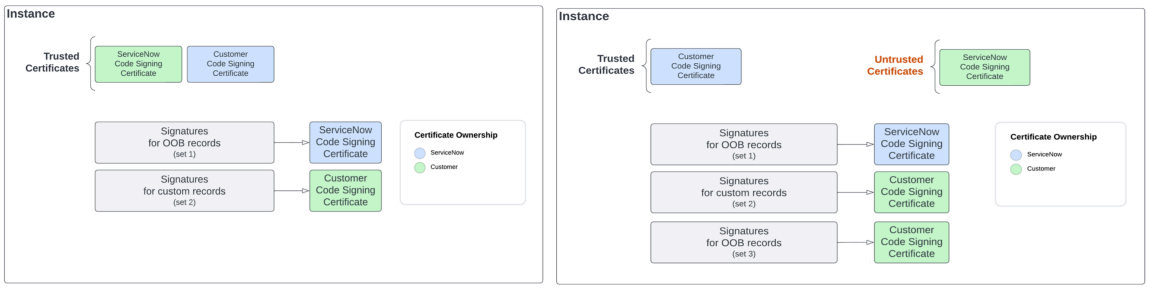
4. Restart the MID Server.

Change your Root of Trust configuration

Trust and use your own certificates instead of relying on ServiceNow build certificates (default) by changing to use your Root of Trust (ROT). ServiceNow components like script includes, business rules, etc., are signed at build time using a ServiceNow build time key (verification certificate is the ServiceNow build certificate).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Changing the root of trust



To change the Root of Trust for these records signatures, you must follow the change of Root of Trust process.

- Generate and migrate a new set of signatures for all provided components, using your provided certificate.
- Disable the Root of Trust property using a scheduled job.

Learn more about these steps in Migrate signatures to use a customer certificate and Disable ServiceNow Root of Trust.

Impact on the signature generation and verification process

By default, Code Signing build certificates are trusted during the signature verification process. After making this change, your instance accepts signatures only from your own Code Signing certificate.

ROT property set to false (default)	ROT property set to true
• When verifying, signatures with build certificates are trusted. • When signing, if you don't provide keys, the instance signing key is used as a backup key. • The signature REST end point *api/sn_kmf/signature/certificates* returns ServiceNow Code Signing build certificates along with other certificates present on the instance.	• When verifying, signatures with build certificates aren't trusted. • When signing, if you don't provide keys, signing isn't performed. • The signature REST end point *api/sn_kmf/signature/certificates* excludes ServiceNow build certificates (San Diego, Vancouver PKI, W PKI).

Impact on your MID Server

When the ROT property is set to false

If you choose to leave your ROT property at its default value (false), there's no impact on your MID Server.

When Code Signing is enabled and the ROT property is set to true

- The *isTrusted()* API returns `false` for signatures with a build certificate.
- The *isTrusted()* API returns `true` for signatures with your certificate.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- The REST API call for certificates excludes build certificates.
- You may see MID Server issues, such as `signature validation failed` messages in the logs.

Migrate signatures to use a customer certificate

Run a signing job to migrate your signatures to a customer Root of Trust (ROT).

Before you begin

Role required: admin, security_admin, and sn_kmf.cryptographic_manager

Code Signing must be enabled on your protected and trusted instances. You can verify by checking that the **com.snc.kmf.signature.validation.flag** system property is set to `true`.

This procedure is part of a series of procedures to change a customer Root of Trust (ROT) on your instances. For an overview of this process, see Change your Root of Trust configuration.

Procedure

1. Log in to your protected instance.
2. Navigate to **All** > **System Definition** > **Scheduled Jobs**.
3. Find and open the **ROT - Generate Updateset of records to migrate signatures using customer certificate** scheduled job.
4. At the bottom of the form, select **Execute Now**.
5. Navigate to **All** > **System Security** > **Security Jobs** > **Create New**.
6. At the prompt, select **Signing Job**.
7. In the **Signing Job** form, fill in the fields as needed.

Field	Value
Name	Create a unique name for your job.
Type	Select **Sign Update Set**.
Table	Select the update set created in the previous steps. The update set has a name beginning with `change_root_of_trust_updateSet`.

8. Right-click the form header and select **Save** to save this record.
9. Right-click the form header and select **Export** > **XML (This Record)** to export this record as an XML file.
10. Log in to your trusted instance.
11. Navigate to **All** > **System Security** > **Security Jobs** > **All**.
12. Right-click the list header and select **Import XML**.
13. In the **Import XML** form, select **Choose File** and select the XML file you downloaded in the previous steps.
14. Select **Upload**.
15. From the list, open the imported security job.
16. Select **Export Code Signing job to production**.
    This action signs the job and places it in a new update set you can import into your protected instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important: After signing the job, you must perform the next steps within 10 minutes. If you exceed this time period, you can re-sign the job using these steps, which creates another signed update set.

17. Navigate to **All** > **System Update Sets** > **Local Update Sets**.
18. Find the update set created in the previous steps.
    The name starts with `SIGN_UPDATE_SET_updateSet`.
19. Select **Export XML** to export your update set as an XML file.
20. Log in to your protected instance.
21. Navigate to **All** > **System Update Sets** > **Retrieved Update Sets**.
22. At the bottom of the list, select **Import Update Set from XML**.
23. In the **Import XML** form, select **Choose File** and select the XML file you downloaded in the previous steps.
24. Select **Upload**.
25. Navigate to **All** > **System Update Sets** > **Retrieved Update Sets**, and open the update set starting with `SIGN_UPDATE_SET_updateSet`.
26. Select **Preview Update Set**.
27. After the preview is completed, select **Commit Update Set**.
28. Navigate to **All** > **System Security** > **Security Jobs** > **All**.
29. Open the imported security job.
30. Select **Start** to run the security job.

    After the security job is completed, information regarding the status of the job appears in the **Summary** field.

    When the job is in Done state, all signatures of update set records must use the customer provided certificate as verification certificate. You can verify this on the KMF Signature Records [sn_kmf_record_signature] table.

What to do next

To continue the Root of Trust configuration process, see Disable ServiceNow Root of Trust.

Disable ServiceNow Root of Trust

Run a scheduled job on your trusted instance to disable Root of Trust.

Before you begin

Role required: admin, security_admin, and sn_kmf.cryptographic_manager

Code Signing must be enabled on your protected and trusted instances. You can verify by checking that the **com.snc.kmf.signature.validation.flag** system property is set to `true`.

This procedure is part of a series of procedures to change to a customer Root of Trust (ROT) on your instances. For an overview of this process, see Change your Root of Trust configuration.

Procedure

1. Log into your trusted instance.
2. Navigate to **All** > **System Definition** > **Scheduled Jobs**.
3. Open the **Disable ServiceNow Root of Trust** scheduled job.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Select the **Export signed job to production**.
5. Navigate to **All** > **System Update Sets** > **Local Update Sets**.
6. Find and open the **Disable ServiceNow Root of Trust** update set.
7. Select **Export XML** to export your update set as an XML file.
8. Log in to your protected instance.
9. Navigate to **All** > **System Update Sets** > **Retrieved Update Sets**.
10. At the bottom of the list, select **Import Update Set from XML**.
11. In the **Import XML** form, select **Choose File** and select the XML file you downloaded in the previous steps.
12. Select **Upload**.
13. Navigate to **All** > **System Update Sets** > **Retrieved Update Sets**, and open the **Disable ServiceNow Root of Trust** update set.
14. Select **Preview Update Set**.
15. After the preview is completed, select **Commit Update Set**.
16. Navigate to **All** > **System Definition** > **Scheduled Jobs**.
17. Open the scheduled job imported in the update set.
18. Select the **Execute Now** button to run the job.

Result
Executing the scheduled job sets the ROT property to true. Your instance is configured to use the customer root of trust.

Using Code Signing

Learn how to sign records, messages, and attachments to help verify the authenticity and integrity of your data.

Sign the JDBC data source records in the protected instance

Use update sets to sign and validate the JDBC data sources by enabling the code signing in protected and trusted instances.

Sign the REST and SOAP messages in the production instance

Use update sets to sign and validate the REST and SOAP messages by enabling the code signing in protected and trusted instances.

Sign the flows, subflows, and actions in the protected instance

Use update sets to sign and validate the flows, subflows, and actions by enabling the Code Signing in protected and trusted instances.

Sign specific records or attachments

Create a security job to sign specific records or attachments rather than all records or attachments on a table.

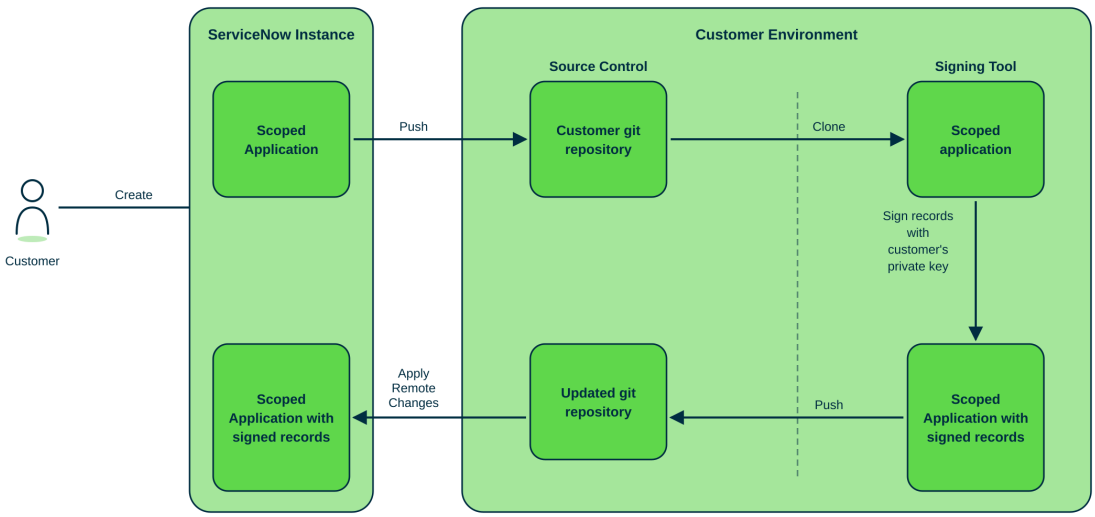
Standalone signing tool

Use the standalone Signing Tool to sign supported records in ServiceNow applications using your own private key.

Signature generation during source control commit

Generate signatures automatically when you commit application files to source control from a trusted instance in ServiceNow Studio. The signatures are added to

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



the same update set as their source records and pushed to the remote repository together.

Standalone signing tool

Use the standalone Signing Tool to sign supported records in ServiceNow applications using your own private key.

Use the Signing Tool to sign records in ServiceNow apps. The tool generates signatures for records in your local environment using your own private key.

Signing tool workflow

1. Create or select an existing ServiceNow application with records to be signed, such as business rules or script includes.
2. Push the application into your Git repository, which resides in your environment.

   Note: Applications can be synced between a Git repository and your instance using the Source Control Integration. For details on configuring and using this integration, see .

3. Clone the application in your local environment.
4. Use the Signing Tool (also in your local environment) to sign the supported records from the cloned ServiceNow application using your private key. The Signing Tool creates signature records and X.509 Certificate [sys_certificate] records. For details on using the Signing Tool, see Using the Signing Tool.
5. Push the updated application to your Git repository.
6. In your instance, import the updated application by applying remote changes.

Using the Signing Tool

Learn how to use the Signing Tool to sign supported records in ServiceNow applications.

Before you begin
Role required: admin

To perform these steps, you must have the following:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- A ServiceNow application that has records to be signed.
- A private key for signing records.
- The *signRecords.sh* script in your local environment, with execute permission.

Important: The *signRecords.sh* script is included as part of the signing-tool jar file, which you must request from ServiceNow customer support.

Procedure

1. In your local environment, navigate to the directory containing the *signRecords.sh* script.
2. Use the following command format to sign your records:

```
./signRecords.sh -d [Path to the root directory of the
 ServiceNow Application to Sign] -f [Path to the Keystore file]
```

   For example:

```
./signRecords.sh -d /users/abc/ServiceNow-App-1
 -f /users/abc/codesigning.p12
```

3. If prompted, enter the password for the keystore.
   Press Enter if there's no password.
4. Review the output to confirm a successful signing.

```
Sep 26, 2022 2:41:09 PM com.snc.java.commands.ACommand start
INFO: CODESIGN: executing codesigning...
Sep 26, 2022 2:41:09 PM
 com.snc.core.codesigning.CodeSignerSupplier get
INFO: CODESIGN: signing record for documentId:
 65e81132770211057416efe7c5a994f
Sep 26, 2022 2:41:11 PM com.snc.java.commands.ACommand start
INFO: CODESIGN: codesigning successfully completed!
```

   In the preceding output example, the Signing Tool used the provided keystore file to sign the record. You can also see that:

   - The script found a supported record `65e81132770211057416efe7c5a994f` and signed it.
   - In the ServiceNow-App-1 directory, two records created: `sys_certificate.xml` and `sn_kmf_record_signature.xml`.
5. Import the updated application back into your instance by applying remote changes in Studio. For more information, see .

Signing Tool arguments

Learn about the available arguments for the Signing Tool.

Command line arguments

Argument	Required	Description
-d	Yes	Root directory of project to sign. Should contain project directory (random 32 alphanumeric), sn_source_control.properties file, and a <project_name>.iml file
-f	Yes	The file path of the keystore.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Command line arguments (continued)

Argument	Required	Description
-a	No	Alias used to access a specific entry within the keystore.
-c	No	Concatenate record signatures into one file.
-k	No	Password to access the key stored within the keystore. You can also enter this password when prompted instead of within the argument.
-o	No	Sign with a new certificate in place of any existing sys_cert files.
-p	No	Password to access the keystore if it has a password. You can also enter this password when prompted instead of within the argument.
-w	No	Wipe all existing signature record files.
-h	No	Show this help message and exit.

Sign the JDBC data source records in the protected instance

Use update sets to sign and validate the JDBC data sources by enabling the code signing in protected and trusted instances.

- Establish Circle of Trust between the protected and trusted instances.
- Role required: security_admin

Note:

- MID Server doesn't handle the file data sources and hence, these data sources are not code signed.
- LDAP data sources can't be code signed.

Sign existing data sources of the JDBC type

Use update sets to bring mass signing jobs to the protected instance.

Before you begin

Role required: security_admin

Procedure

1. In the trusted instance, configure the KMF signing job to sign the data sources.

   a. Navigate to **System Security** > **Security Jobs** > **All**.

   b. Click **New**.

   c. On the form, fill these values.

Field	Description
Name	Name to identify the record.
Type	Type of the encryption job. Select **Mass Sign Records**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Table	Table from which the records should be signed. Select **Data Source**.

d. Click **Export Code Signing job to production**.
A confirmation message is displayed that the update set is signed.

e. Export the generated update set to an XML file.

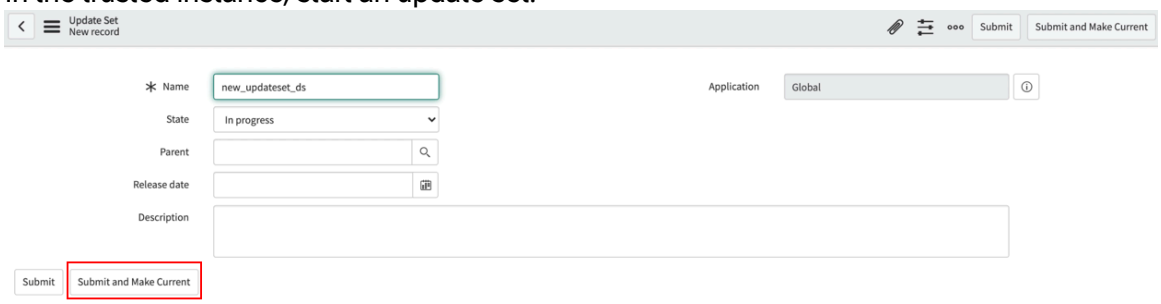
2. In the protected instance, import and commit the update set to retrieve the mass signed jobs from trusted instance.

a. Navigate to **System Security** > **Security Jobs** > **All**.

b. Open the update set exported from the trusted instance.

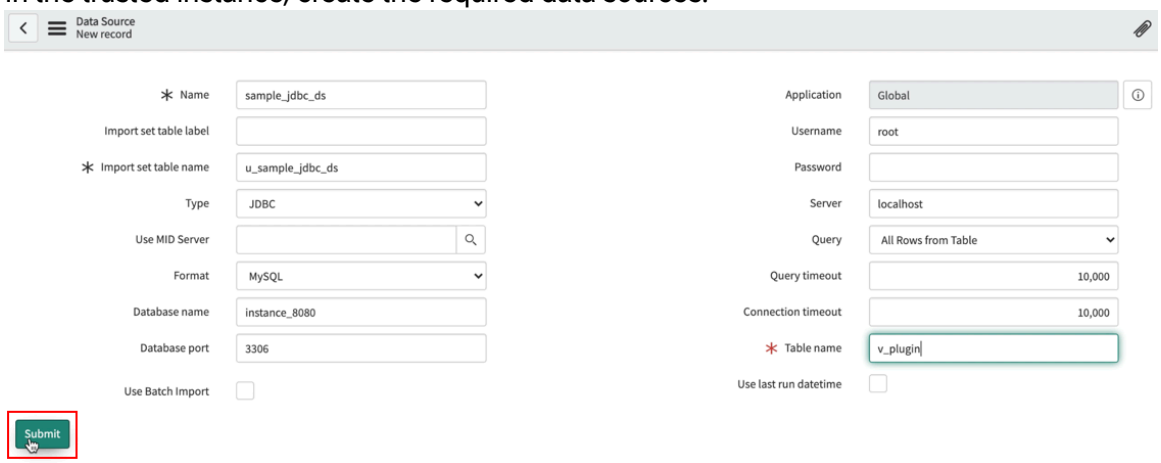
c. Click **Start**.
A confirmation message is displayed that the records are signed.

Sign new data sources of the JDBC type



Use update sets to bring the signed update set to the protected instance.

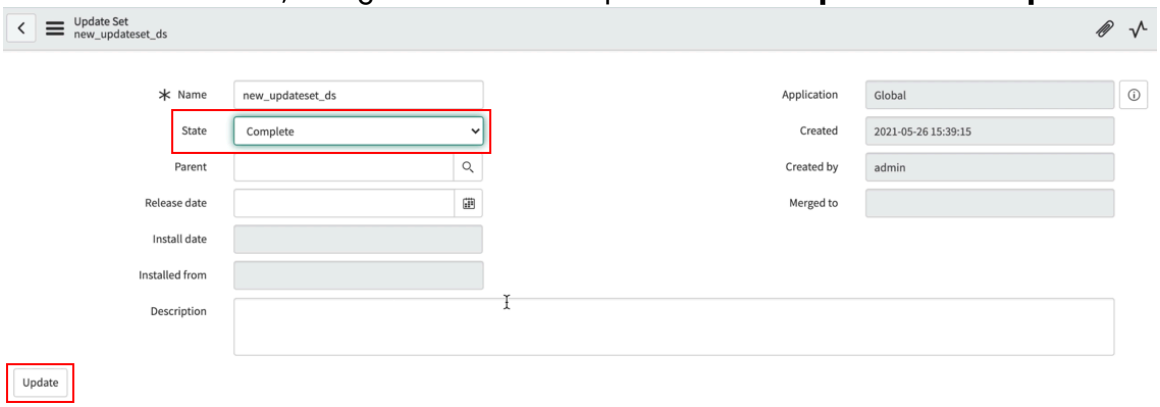
Before you begin



Role required: sn_kmf.cryptographic_manager

Procedure

1. In the trusted instance, start an update set.

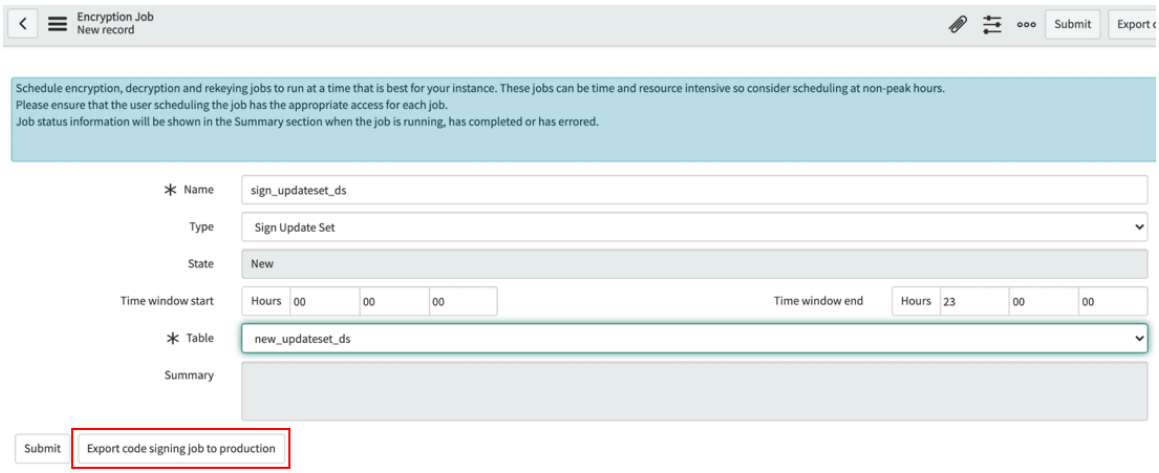


2. In the trusted instance, create the required data sources.

The data sources are added to the update set.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. In the trusted instance, change the state of the update set to **Complete** and click **Update**.

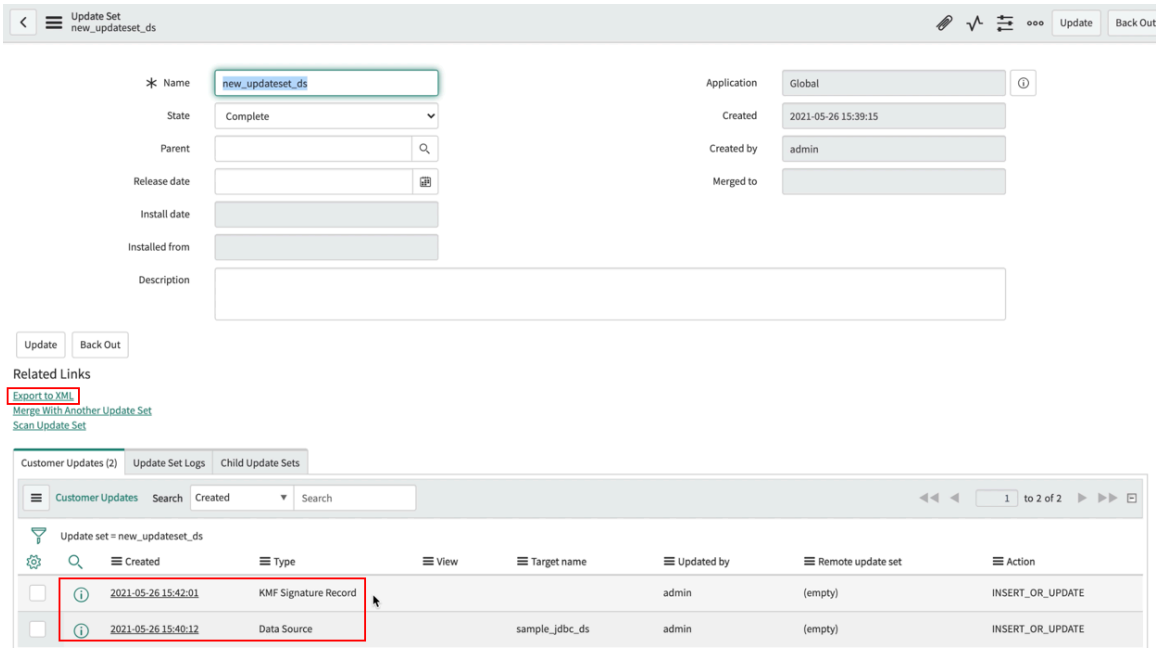


4. In the trusted instance, sign the update set by creating an encryption job.

   a. Navigate to **System Security** > **Security Jobs** > **All**.

   b. Click **New**.

   c. On the form, fill these values.



Field	Description
Name	Name to identify the record.
Type	Type of the encryption job. Select **Sign Update Set**.
Table	Update set from which the records should be signed.

   d. Click **Submit**.

   e. Click **Start** to sign the update set.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Summary** is updated that the records are signed.
- The update set is updated and includes the signature.

5. In the trusted instance, open the signed update set record and export it to an XML.
6. In the protected instance, import the signed update set.

   a. Navigate to **System Update Sets** > **Retrieved Update Sets**.

   b. Click the **Import Update Set from XML** related link to import the update set that is exported from the trusted instance.
   For more information, see Import and commit the quick-start update set.
   The update set is committed successfully.

Sign the REST and SOAP messages in the production instance

Use update sets to sign and validate the REST and SOAP messages by enabling the code signing in protected and trusted instances.

Before you begin

- Establish Circle of Trust between the protected and trusted instances.
- Role required: security_admin

Sign the existing REST and SOAP messages

Sign and validate the existing REST and SOAP messages by enabling the Code Signing in protected and trusted instances.

Before you begin

Role required: sn_kmf.cryptographic_manager

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. In the trusted instance, configure the KMF signing job to sign the UI actions.

   a. Navigate to KMF Signature Configuration.

   b. On the form, fill these values.

   KMF Signature Configuration form

Field	Description
Table Name	Glide table name. For example, select **UI Actions [sys_ui_action]**.
KMF Signature Purpose	Purpose of signing the records. Select **ECC Queue**.
Signature Generation Fields	Fields in the data source that you want to sign. If any changes are made to the values in one or more of these fields, the previously generated signature becomes invalid. Select **Name** and **Script**.
Signature Generation Filter	Filter criteria that must be met to sign the records.
Sign Attachment	Option to sign the attachment in the glide record.
Instance Key	Option to use the instance key.

   c. Right-click the form header and click **Save**.

2. In the trusted instance, sign the required records.

   a. Navigate to **System Security** > **Security Jobs** > **All**.

   b. Click **New**.

   c. On the form, fill these values.

Field	Description
Name	Name to identify the record.
Type	Type of the encryption job. Select **Mass Sign Records**.
Table	Table from which the records should be signed. Select **UI Action**.

   d. Click **Export Code Signing job to production**.
   Two locally signed update sets are created.
   - One update set for the UI action configuration.
   - Another update set from the encryption job to export the code signing job.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. In the trusted instance, export the local update set to an XML file.
   a. Navigate to **System Update Sets** > **Local Update Sets**.
   b. Open the update set you had created for mass signing the records.
   c. Click the **Export to XML** related link and save the XML file.
4. In the protected instance, import the update sets.
   a. Navigate to **System Update Sets** > **Retrieved Update Sets**.
   b. Click the **Import Update Set from XML** related link to import the update set that is exported from the trusted instance.
   For more information, see Import and commit the quick-start update set.
   The update set is committed successfully.
5. In the protected instance, run the encryption job you had earlier created in the trusted instance by selecting **Start**.
   A confirmation message is displayed mentioning that the records are signed.

Sign new REST and SOAP messages

Sign and validate the new REST and SOAP messages from the trusted instance by enabling the Code Signing in protected and trusted instances.

Before you begin

Role required: security_admin

Procedure

1. In the trusted instance, start an update set.
2. In the trusted instance, create the required REST or SOAP messages.
   The messages are added to the update set.
3. In the trusted instance, change the state of the update set to **Complete** and click **Update**.
4. In the trusted instance, sign the update set by creating an encryption job.
   a. Navigate to **System Security** > **Security Jobs** > **All**.
   b. Click **New**.
   c. On the form, fill these values.

Field	Description
Name	Name to identify the record.
Type	Type of the encryption job. Select **Sign Update Set**.
Table	Update set from which the records should be signed. Select **Sign new Rest V2 update set - 1**.

   d. Click **Submit**.

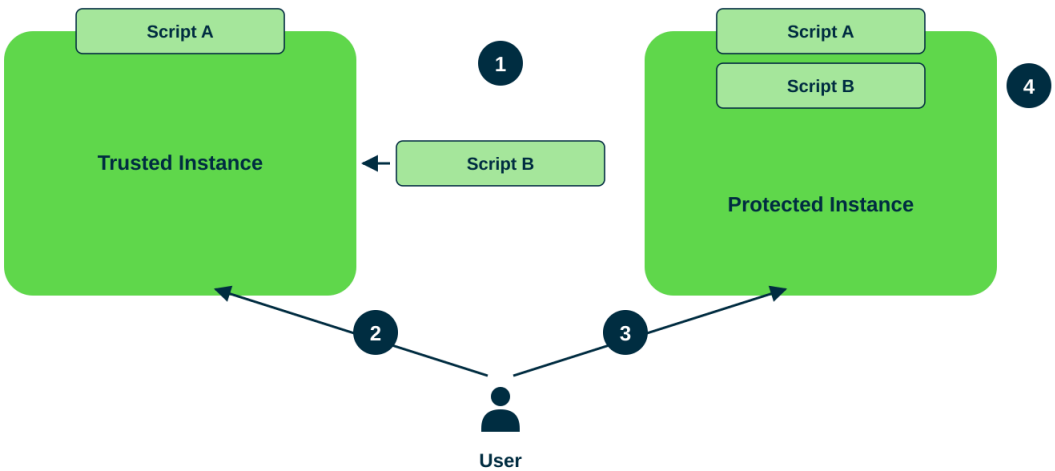
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

e. Click **Start** to sign the update set.
   - **Summary** is updated that the records are signed.
   - The update set is updated and includes the signature.

5. In the trusted instance, open the signed update set record and export it to an XML.
6. In the protected instance, import the update set.

   a. Navigate to **System Update Sets** > **Retrieved Update Sets**.

   b. Select the **Import Update Set from XML** related link to import the update set that is exported from the trusted instance.
   For more information, see Import and commit the quick-start update set.
   The update set is committed successfully.



Sign specific records or attachments

Create a security job to sign specific records or attachments rather than all records or attachments on a table.

Beginning in the Vancouver release, security administrators can use security jobs to sign specific records on a table rather than all records on a table. Sign specific records to avoid accidentally signing any unreviewed code.

These jobs include an attached log file, which is generated at the end of the signing job. This log file contains information about signed records and the signature configuration used.

Signing process

This diagram shows an example of how you can use the signing process. In this example, a script, labeled `Script B` exists only on the protected instance, and must be imported to a trusted instance to be signed. `Script A` exists on both instances already, doesn't need to be signed. It has either already been reviewed and signed, or hasn't been reviewed yet and shouldn't be signed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

1. Import the record to your trusted environment.
2. In the trusted instance, create a signing job to sign the record. This process is detailed in Create a job to sign specific records or attachments on a trusted instance.
3. Import the signed signing job to your protected instance using an update set.
4. In the protected instance, run the imported signing job.

Create a job to sign specific records or attachments on a trusted instance

Sign a specific record, or group of records you define on a trusted instance.

Before you begin

Role required: security_admin or sn_kmf.cryptographic_manager

Procedure

1. Navigate to **All** > **System Security** > **Security Jobs** > **Create New**.
2. At the **What type of Security Job would you like to create?** prompt, select **Signing Job**. A new **Signing Job** record displays.
3. In the form, fill in the fields as needed:

Signing job fields

Field	Description
Name	Descriptive name for this job.
Type	Type of security job. To sign specific records, select the **Sign Specific Records** option. To sign specific attachments, select **Sign Specific Attachments**.
State	State of this job. This field begins with the value of **New**. This field is read only.
Table	Table containing the records or attachments you want to sign. If signing attachments, select the table with records that the attachments are associated with, not the Attachment [sys_attachment] table. **Tip:** Check the Key Management Framework (KMF) Signature Record [sn_kmf_record_signature] table to ensure that there aren't already signatures for the table you've selected.
Filter Records	Filter conditions used to limit which records appear in the **Select records for signing** table.
Select records for signing	List of records on the table selected in the **Table** field, limited by filter created in the **Filter Records** field. Move records from the **Available** window to the **Selected** window to include them in the signing job.
Time window start	The start of the time window to run this job. The job will run after the time entered in this field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	A valid time value is in Coordinated Universal Time based on a 24-hour time notation.
Time window end	The end of the time window to run this job. The job runs before the time entered in this field. If the job hasn't yet completed, the job will pause and resume at the next time window start. The end time must be after the start time. A valid time value is in Coordinated Universal Time based on a 24-hour time notation.
Summary	Summary of the execution of this job. This field is read only.

4. Right-click the form header, and select **Save**.
5. Open the job that you saved, and click **Start**.
   This action signs the signing job, and it's ready for export.
6. Navigate to **All** > **System Update Sets** > **Local Update Sets**
7. Find and open the update set for your signing job.
   In the customer updates tab, you can see that this update set includes the signing job and the signature record.
8. Select **Export to XML**.
   This action creates an XML file containing your update set on your local device.
9. On your protected instance, navigate to **All** > **System Update Sets** > **Retrieved Update Sets** > **.**
10. At the bottom of the page, select **Import Update Set from XML**.
11. Select the **Choose File** button, and select the XML file created in previous steps.
12. Select **Upload**.
    Your update set is loaded, and appears in the **Retrieved Update Sets** list.
13. In the **Retrieved Update Sets** list, open the record for your imported update set.
14. Select the **Preview Update Set** button.
    After the preview completes successfully, you'll see the **Commit Update Set** button appear.
15. Select **Commit Update Set**.

Signature generation during source control commit

Generate Code Signing signatures automatically when you commit application files to source control from a trusted instance. The signatures are added to the same update set as their source records and are pushed to the remote repository together.

Signature generation during commit

Signature generation during source control commit adds signing as an inline step in the application commit flow. When you commit selected files from an application in ServiceNow Studio, the trusted instance generates a signature for each eligible record. The files then advance to the commit confirmation screen. The source records and their signatures are committed to the same update set and pushed to the remote repository together. A commit can't complete while a signature is missing for a selected record, so every record pushed to the repository has a signature.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Without this feature, records are committed to source control without signatures. Signatures are then generated in a separate step through the mass signing jobs, and they don't travel with the source records. As a result, an instance that imports the records can't validate them against a signature that was committed alongside them.

How it works

During a commit, the trusted instance first verifies that it's eligible to generate signatures. If the instance is eligible, it generates a signature for each selected record that matches a signature configuration, including the record's attachments and embedded Flow Designer records. Each generated signature is written to the same update set as its source record, so the source records and their signatures are committed together. For example, five selected records produce five signatures, for a total of ten files to commit.

Eligibility for signature generation

A trusted instance generates signatures during commit only when all of the following conditions are met:

- The feature is turned on for the instance.
- The instance is opted in to Code Signing, which occurs when the Code Signing Enterprise plugin is installed.
- The instance isn't enforcing signature validation. Signatures can be generated only on a trusted instance, not on a protected instance.
- A code signing crypto module with an active signing key exists, which occurs after you upload the signing certificate during the Circle of Trust guided setup.

Note:

If an instance isn't eligible, the commit flow runs as it does without the feature. No signatures are generated and no error appears. This behavior keeps the commit flow unchanged for instances that don't use Code Signing.

Considerations

- Signature generation during commit applies to records committed from an application in ServiceNow Studio. To sign records created directly on the instance, use the mass signing jobs or the Standalone Signing Tool.
- Records with a delete action aren't signed during commit. If such a record has a previous signature, that signature isn't included in the update set and is removed by the orphan signatures cleanup job.
- This feature generates signatures. It's works independently of signature validation, which is the separate enforcement step performed on a protected instance.

Related topics

Generate signatures when committing to source control

Generate signatures when committing to source control

Turn on signature generation during commit and commit application files from ServiceNow Studio. Eligible records are signed automatically and pushed to the remote repository with their signatures.

Before you begin
Before you begin:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Install the Code Signing Enterprise plugin. For more information, see Configuring Code Signing
- Complete the Circle of Trust guided setup on the trusted instance, including uploading your signing certificate.
- Perform this task on a trusted instance. Signatures can't be generated on a protected instance.
- Link the application to source control in ServiceNow Studio. For more information, see Link an app to source control in ServiceNow Studio

Role required: codesigning_admin (to turn on the property only)

About this task

Turn on signature generation during commit so that a trusted instance signs eligible records as part of the source control commit. The signatures are added to the same update set as their source records and pushed to the remote repository together.

Procedure

1. In the navigation filter, enter `sys_properties.list` and press Enter.
2. Open the *sn_cse.com.snc.csf.generate_signature_commit* property.

   This property turns signature generation during commit on or off. It ships with a value of `false`.
3. Set the value to `true` and save the property.
4. Open your application in ServiceNow Studio.
5. Create or update the records to commit.
6. Select **Source Control** > **Commit changes**.

   The Commit changes dialog box lists the created or updated files for the application, grouped by update set.
7. Select the files to commit, and then select **Continue**.

   The instance generates a signature for each eligible selected record.
8. Review the source records and their signatures on the confirmation screen.
9. Enter a commit comment.
10. Select **Commit files**.

Result

The instance pushes the source records and their signatures to the remote repository together. Each committed record has a corresponding signature record in the repository.

Trouble?

If a signature can't be generated for a selected record, for example because of a network issue, the confirmation screen doesn't open. You remain on the file selection screen and an error message identifies the record. Select **Continue** to retry signature generation for the failed record.

Sign the flows, subflows, and actions in the protected instance

Use update sets to sign and validate the flows, subflows, and actions by enabling the Code Signing in protected and trusted instances.

- Establish Circle of Trust between the protected and trusted instances.
- Role required: security_admin

Sign the existing flow, subflows, and actions

Sign and validate the existing flow, subflows, and actions by enabling the code signing in production and trusted instances.

Before you begin

Role required: sn_kmf.cryptographic_manager

Procedure

1. In the trusted instance, sign the records in the Step Instance table.
   a. Navigate to **System Security** > **Security Jobs** > **All**.
   b. Click **New**.
   c. On the form, fill these values.

Field	Description
Name	Name to identify the record.
Type	Type of the encryption job. Select **Mass Sign Records**.
Table	Table from which the records should be signed. Select **Step Instance**.

   d. Click **Export Code Signing job to production**.
   Two locally signed update sets are created.
   - One update set for the KMF signature.
   - Another update set from the encryption job to export the code signing job.

2. In the trusted instance, export the local update set to an XML file.
   a. Navigate to **System Update Sets** > **Local Update Sets**.
   b. Open the update set you had created for mass signing the records.
   c. Click the **Export to XML** related link and save the XML file.
3. In the protected instance, import the XML file.
   a. Navigate to **System Update Sets** > **Retrieved Update Sets**.
   b. Click the **Import Update Set from XML** related link to import the update set that is exported from the trusted instance.
   For more information, see Import and commit the quick-start update set.
   The update set is committed successfully.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. In the protected instance, run the encryption job you had earlier created in the trusted instance.
   a. Navigate to **System Security** > **Security Jobs** > **All**.
   b. Open the encryption job you had earlier created in the trusted instance.
   c. Click **Start** to start the job.
   A confirmation message is displayed mentioning that the records are signed.

Sign new flow, subflows, and actions

Sign and validate new flow, subflows, and actions by enabling the Code Signing in protected and trusted instances.

Before you begin

Role required: sn_kmf.cryptographic_manager

Procedure

1. In the trusted instance, start an update set.
2. In the trusted instance, create the required flows, subflows, or actions, and publish them.
   The flows, subflows, or actions are added to the update set.
3. In the trusted instance, change the state of the update set to **Complete** and click **Update**.
4. In the trusted instance, sign the update set by creating an encryption job.
   a. Navigate to **System Security** > **Security Jobs** > **All**.
   b. Click **New**.
   c. On the form, fill these values.

Field	Description
Name	Name to identify the record.
Type	Type of the encryption job. Select **Sign Update Set**.
Table	Update set from which the records should be signed.

   d. Click **Submit**.
   e. Click **Start** to sign the update set.
      - **Summary** is updated that the records are signed.
      - The update set is updated and includes the signature.
5. In the trusted instance, open the signed update set record and export it to an XML.
6. In the protected instance, import the signed update set.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Navigate to **System Update Sets** > **Retrieved Update Sets**.

b. Select the **Import Update Set from XML** related link to import the update set that is exported from the trusted instance.
For more information, see Import and commit the quick-start update set.
The update set is committed successfully.

Signature Verification in Code Signing

Signature verification helps confirm that records, scripts, and other signed content originate from trusted sources and remain unaltered.

Signature Verification process

Signature verification is a core part of Code Signing. When the MID Server processes a signed record or script, it checks the attached digital signature against the certificate used to generate it. This verification helps confirm that the content is authentic and hasn't been modified since it was signed. If the signature is valid and the certificate is trusted, the system permits the operation. If the signature is invalid or the certificate is untrusted, the system blocks execution to protect the environment.

Support for multiple signatures per record

With the Australia release, there's enhanced support for verifying multiple signatures on a single record. A record might collect signatures over time from different certificates, such as customer-owned certificates and ServiceNow® build certificates. To provide more accurate verification, the system now groups signatures by certificate and evaluates the most recent signature in each group. Compared to the previous model, which evaluated only the most recent signature on the record, this approach provides a more reliable verification process.

Verification succeeds if any certificate group contains a valid latest signature. This improvement ensures that a valid signature from one certificate isn't overlooked simply because a newer signature from another certificate is invalid. This approach helps avoid failures after upgrades and helps recognize all valid signatures from any trusted source.

Code Signing Health and Status Dashboard

The Code Signing Health and Status dashboard provides a centralized, user-friendly view of your Code Signing environment's health and configuration. Use it to identify issues, verify configuration accuracy, and support secure, uninterrupted code-signing operations.

The Code Signing Health and Status dashboard highlights configuration issues and includes intuitive guidance to help you resolve them quickly, reducing the need for escalation. You can use the dashboard to verify that Code Signing configurations are set up correctly and performing securely. It helps you identify potential issues that could lead to failures and enables you to provide accurate guidance to the stakeholders involved.

The dashboard lets you search, filter, and rescan the following parameters:

- Configurations
- Certificate status
- Plugin details
- Signature verification certificate
- MID Server setup

Overview Dashboard

The Overview dashboard provides a centralized view of your Code Signing environment, offering real-time insights into key components and their status.

The Overview dashboard displays the following reports:

Overview Dashboard

Title	Type	Description
Enterprise plugin	Text field	Status of essential plug-ins and system properties required for Code Signing functionality. **Enterprise plugin** displays the core plugin needed for signing operations.
Opt-in property	Text field	Configuration flag that enables Code Signing capabilities. **Note:** This setting must be **Active** to confirm that code signing functions according to the specific requirement.
Signature validation status	Text field	Indicates whether signature validation is enforced during code execution to verify that only the trusted scripts are executed.
Signature states	Pie chart	Comprehensive overview of all the script signatures, including their current validation status. The signatures are categorized into: • **Trusted** signatures are valid and associated with trusted code signing certificate. • **Untrusted** signatures fail validation or are linked to untrusted verification certificate.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Overview Dashboard (continued)

Title	Type	Description
		• **Orphan** signatures are present but no longer linked to a known or active certificate. **Note:** Use this information to assess script integrity and take corrective action as needed.
MID Server configuration state	Pie chart	Status and trust relationship of all the MID Servers in your instance. Use this section to view the total number of MID Servers and check their status. • **Active MID Servers**: The number of servers that are currently running and successfully connected. • **Inactive MID Servers**: The number of servers that aren't running or are disconnected.
Signed records by type	Pie chart	Distribution of signed records by record type, showing the percentage coverage across the following categories: • **Business Rules**: The percentage of signed business rule records. • **Script Includes**: The percentage of signed script include records. • **Others**: The percentage of signed records in other supported categories.
Signed records by application	Pie chart	Distribution of signed records across different application

Title	Type	Description
		modules, showing the percentage of code signing coverage. • **User Management**: Percentage of signed records in the User Management module. • **Form Validation**: Percentage of signed records related to form validation. • **Others**: Percentage of signed records in all other application modules.

Signature Verification Status

View the status of valid, invalid, and missing signatures across different applications to assess code signing coverage. Use this information to identify areas that may require additional attention or action.

The Signature Verification Status dashboard displays the following reports:

Signature Verification Status Dashboard

Title	Type	Description
Script name	Text field	Identifier or title assigned to a specific script within the system.
Type	Text field	Category of the script within the system. It helps define the role and functionality of the script. Example: • Business rule • Script include • Client script • Flow action
Application	Text field	Module or area within the system where the script is applied. Example: • User management • Reporting

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Signature Verification Status Dashboard (continued)

Title	Type	Description
		• Form validation • Workflow • Notifications
Status	Text field	Indicates the current verification status of the script signature. • **Valid**: The script signature is verified and is trusted. • **Invalid**: The script signature isn't verified or is deemed untrusted. • **Missing**: The source document is eligible for signing but doesn't have a signature yet. Use this status to identify eligible records that remain unsigned and require code signing.
Last scanned	Text field	Date and time when the script was last scanned for signature verification in the format: `DD/MM/YY/H:S (Day/Month/Year/ Hour:Minute)`

Code Signing MID Server Configuration

Manage and configure the trust relationships and certificate settings for MID Servers.

The Code Signing MID Server Configuration dashboard displays the following reports:

Code Signing MID Server Configuration

Title	Type	Description
MID Server	Text field	Name of the specific MID Server instance.
Status	Text field	Current operational state of the MID Server. • **Active** • **Inactive**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Code Signing MID Server Configuration (continued)

Title	Type	Description
Version	Text field	Software version of the MID Server currently in use. Use this information to: • Ensure compatibility with your instance. • Ensure that the server is running the latest supported features and security updates.
Last check-in	Text field	Most recent date and time that the MID Server successfully communicated with the instance in the following format: `DD/MM/YY/H:S (Day/Month/Year/ Hour:Minute)`

Key Pair and Certificates

The Key Pair and Certificates dashboard displays details about the cryptographic keys and digital certificates used for Code Signing. It includes information such as key type, certificate issuer, expiration date, and validity status. Use this dashboard to manage code signing certificate credentials, verify their validity, and help ensure secure and trusted Code Signing operations.

The Key Pair and Certificates Configuration dashboard displays the following reports:

Key Pair and Certificates Configuration

Title	Type	Description
Certificate Name	Text field	The unique identifier (name) assigned to a digital certificate used for Code Signing.
Crypto Module	Text field	The cryptographic component used to generate, store, and perform key operations on private keys for Code Signing. It ensures secure key operations and helps protect sensitive cryptographic material from unauthorized access.
Type	Text field	The classification of the cryptographic key or certificate used for Code Signing. Example:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Key Pair and Certificates Configuration (continued)

Title	Type	Description
		• ServiceNow • Third party
Expires	Text field	Date when the digital certificate expires and is no longer valid for use.
Status	Text field	Current validity of the digital certificate. • **Valid**: The certificate is active and can be used for Code Signing. • **Expired**: The certificate has passed its expiration date and is no longer valid. • **Expiring Soon**: The certificate is nearing its expiration date. Use this status to take proactive steps for renewal to avoid disruptions in code signing operations.
Chain	Text field	The certificate chain, which includes the digital certificate along with the intermediate and root certificates that establish a trust path. Select **View Chain** to view the certificate chain.

Code Signing Configuration

The Code Signing Configuration dashboard displays the system properties and key settings that control Code Signing in your environment, including flags and enforcement policies. These settings enable features, enforce signature validation, and define trusted sources.

The Code Signing Configuration dashboard displays the following reports:

Code Signing Configuration

Title	Type	Description
Setting	Text field	Name of a specific configuration property that controls a feature or behavior related to code signing. Each setting defines how the system should handle aspects like signature validation,

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Code Signing Configuration (continued)

Title	Type	Description
		enforcement, or trusted sources.
Value	Text field	Current state or input assigned to a specific setting. It determines how the setting behaves. For example, whether Code Signing is enabled (true) or disabled (false). The value directly affects the system's Code Signing operations and enforcement.
Last Updated	Text field	Most recent date and time when the setting was modified in the following format: `DD/MM/YY/H:S (Day/Month/Year/ Hour:Minute)`

Utilities Dashboard

The Utilities dashboard provides a unified workspace to monitor signature status, detect configuration issues and maintain the overall health of your Code Signing environment. It consolidates common Code Signing administrative tasks into a single interface, eliminating the need to navigate across multiple areas of the instance.

You can find detailed explanations on each dashboard tile in these sections.

Maintenance Tasks

Generate batch signatures

You can use this utility to convert a CSV of records with missing or invalid signatures into optimized batches and produce update sets for import to a protected instance.

Generate batch signatures

Automatically generate batch update sets for records with invalid or missing signatures on the trusted instance.

Before you begin

You need the guardrail scan CSV report generated during CoT setup. To rerun the guardrail check, navigate to the **Signature Verification Status** tab in the Health and Status Dashboard. Select the **Rescan** button to start the scan.

Roles required:

- security_admin
- codesigning_admin
- sn_kmf.cryptographic_manager

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task

Upload a CSV file of invalid records from guardrail checks. The utility creates optimized batches and produces signed update sets for download and import. This process streamlines your workflow and eliminates the need to create signing jobs individually.

Procedure

1. Select **+Add file**, select the CSV file from your device, and select the **Upload** button.

   Note: You can modify the CSV file to include only essential records based on organizational priorities.

   The banner displays a success message.
2. Generate update sets by selecting the **Start scan** button.
   The progress bar indicates the status of the update set generation. If you encounter an error, verify the file contents and column names are correct. Confirm the file contains at least one eligible record.
3. Select the **Next** button.
4. Select the **Download all** button.
5. View the update set generation summary by selecting **Download report**.
   The report shows:
   - Update sets created with their names and scope information.
   - Any unsigned records that require attention.
6. Close or complete the session.
   - If you have downloaded all the required update sets, select **Complete**.
   - To return to the session at a later stage, select **Close**.

Result

You can import the downloaded update sets on the protected instance to complete further signing steps.

Code Signing reference

Reference topics provide additional information to administer and troubleshoot Code Signing.

Properties installed with Code Signing

Code Signing adds the following properties.

Roles installed with Code Signing

Code Signing includes the following roles.

Code Signing actions and required roles

Maps every Code Signing action to its required roles and instance type.

Troubleshooting and accessing logs

Access various logs to troubleshoot and identify the failure reasons.

Properties installed with Code Signing

Code Signing adds the following properties.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Type	Description
com.glide.codesigning.expanded.tracking.enabled	true|false	When true, the validation length for the meta stack is increased for ecc_queue topics listed in the **com.glide.codesigning.expanded_tracking.topic.list** property. **Important:** Elevated Security is needed to modify this property.
com.glide.codesigning.expanded.tracking.length	Integer	Levels of Code Signing validation to occur when Code Signing is enabled. The default value is 3. **Important:** Elevated Security is needed to modify this property.
com.glide.codesigning.expanded_tracking.topic.list	String	Comma-separated list of topics to be subject to increased meta-stack tracking. **Important:** Elevated Security is needed to modify this property.
com.glide.codesigning.tables.excluded_from_audit	String	Comma-separated list of tables that are excluded from Code Signing change auditing. Create, update, and delete operations on these tables don't generate an audit record. By default, this property excludes the internal tables that Code Signing uses for certificate storage, cryptographic module and policy configuration, and signing job tracking. For more information, see Code Signing change audit data.
com.glide.codesigning.tracking.agent.validation.exclusion.list	String	Comma-separated list of ecc_queue agents for which Code Signing should be skipped
com.glide.codesigning.tracking.debug	true|false	When true, debug logging for the Code Signing tracker is enabled.
com.glide.codesigning.tracking.enabled	true|false	When true, enables Code Signing caller tracking. **Important:** Elevated Security is needed to modify this property.
com.glide.codesigning.tracking.logging.enabled	true|false	When true, enables logging for Code Signing tracking.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.

Property	Type	Description
com.glide.codesigning.tracking.unsupported_script_tracking	true|false	When true, sc_queue records inserted via unsupported scripts (if detected) aren't notarized. **Important:** Elevated Security is needed to modify this property.
com.glide.codesigning.tracking.validation_fail_fast	true|false	When true, Code Signing verification fails at the first script validation failure instead of verifying all scripts. **Important:** Elevated Security is needed to modify this property.
com.glide.event_handler.code_signing.tracking	String	Defines the Event Handler that helps ensure that customers newly enabling Code Signing are configured to be as secure as possible. **Important:** Elevated Security is needed to modify this property.
com.glide.web_service_outbound.impl.codesigning.tracking	true|false	When true, enables SOAPMessageV2 Code Signing tracking **Important:** Elevated Security is needed to modify this property.
com.snc.csf.maximum_update_size	Integer	The maximum number of records allowed in a Code Signing update set. This value should be limited to a value between 6000 to 10000. If this value is exceeded, multiple update sets are generated and are linked to the same parent update set to enable batch processing. This limitation prevents UI issues described in KB0557104.
com.snc.csf.servicenow_root_of_trust.disabled	true|false	Whether the Root of Trust feature is active. The default value is `false`, meaning that ServiceNow build certificates are trusted. **Important:** This property can only be changed using a signed scheduled job from a user with the admin, security admin and KMF manager roles. For details on changing your Root of Trust, see Change your Root of Trust configuration.
com.snc.kmf.signature.validation.optin	true|false	When true, enables Code Signing on your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Type	Description
		Important: This property can only be changed via a request to Customer Service and Support.
glide.jdbcprobeloader.tracking	true|false	Toggles Code Signing on or off for JDBC data sources. **Important:** Elevated Security is needed to modify this property.
glide.rest.codesigning.tracking	true|false	When true, enables RESTMessageV2 Code Signing tracking. **Important:** Elevated Security is needed to modify this property.
sn_cse.com.snc.csf.vault_audit_enabled	true|false	When true, the platform records create, update, and delete operations on records protected by Code Signing in the *sn_cse_vault_codesigning_audit_data* table. The default value is `true`. For more information, see Code Signing change audit data. **Important:** Only a user with the codesigning_admin role can modify this property.
sn_cse.com.snc.csf.vault_audit_data_max_size	Integer	Maximum number of records that the *sn_cse_vault_codesigning_audit_data* table retains. The default value is 9000. When the record count exceeds this value, the Vault Code Signing Audit Data Cleaner scheduled job deletes the oldest audit records until the count matches this value. **Important:** Only a user with the codesigning_admin role can modify this property.
sn_cse.com.snc.csf.vault_audit_data_retention_days	Integer	Number of days that the *sn_cse_vault_codesigning_audit_data* table retains an audit record. The default value is 90. Values below 30 are treated as 30, and values above 360 are treated as 360.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Type	Description
		Important: Only a user with the codesigning_admin role can modify this property.
sn_cse.com.snc.csf.generate_signature_c	true|false	When true, a trusted instance generates signatures for eligible records during a source control commit from ServiceNow Studio. The default value is `false`. For more information, see Signature generation during source control commit. **Important:** Only a user with the codesigning_admin role can modify this property.

Roles installed with Code Signing

Code Signing includes the following roles.

Code signing admin [codesigning_admin]

Use the code signing admin role to assign codesigning_manager and codesigning_auditor roles to other users.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

Avoid granting an admin role when more specialized roles are available.

Code signing manager [codesigning_manager]

Use the code signing manager role to create and update signature configuration, and create and run code signing jobs.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

None.

Special considerations

None.

Code signing auditor [codesigning_auditor]

Use the code signing auditor role to view signature configurations, signing jobs, and Code Signing change audit data. The auditor role does not have create or write access to code signing assets.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

This role grants read and reporting access to the *sn_cse_vault_codesigning_audit_data* table, which records changes to protected records. No role grants create, update, or delete access to this table. For more information, see Code Signing change audit data.

Code Signing actions and required roles

Reference table of Code Signing actions, their descriptions, and the roles required to perform them.

Role-based access control

Code Signing uses role-based access control so that only authorized users can perform specific actions. The following table maps all Code Signing actions to their required roles.

Unless otherwise noted, all listed roles are required to perform the action.

Role hierarchy

Code Signing includes three primary roles with different levels of access:

codesigning_admin

Highest level access. Can assign codesigning_manager and codesigning_auditor roles to other users and access all configuration features.

codesigning_manager

Operational access. Can create and update signature configurations and create and run Code Signing jobs.

codesigning_auditor

Read-only access. Can view signature configurations, signing jobs, and Code Signing change audit data but can't create or modify them.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Many Code Signing actions also require the security_admin role, which is an elevated role. Users must manually elevate to security_admin by selecting the profile icon and selecting **Elevate Roles**.

Code Signing actions and required roles

Action	Description	Required roles	Instance type
Initial setup and configuration			
Assign Code Signing administrator role	Grant the codesigning_admin role to a user to access the Code Signing configuration experience	admin, security_admin	Both
Configure Code Signing Enterprise on trusted instance	Turn on and configure Code Signing on the trusted instance, including uploading customer signing and COT administration key pairs	admin, security_admin, codesigning_admin, sn_kmf.cryptographic_manager	Trusted
Upload Code Signing configuration file to protected instance	Import the configuration file generated on the trusted instance to the protected instance	admin, security_admin, codesigning_admin, sn_kmf.cryptographic_manager	Protected
Configure Code Signing Enterprise on protected instance	Turn on and configure Code Signing on the protected instance, including uploading the runtime/ notarization key pair	admin, security_admin, codesigning_admin, sn_kmf.cryptographic_manager	Protected
Turn on certificate validation	Protect the instance with certificate-based validation	codesigning_admin, security_admin, sn_kmf.cryptographic_manager	Both
Turn off Code Signing	Disable Code Signing on the protected instance	admin, codesigning_admin	Both
Certificate management			
Create Code Signing key	Create two key pairs and signed	sn_kmf.cryptographic_manager	Trusted

Code Signing actions and required roles (continued)

Action	Description	Required roles	Instance type
View Code Signing Health and Status Dashboard	Monitor overall Code Signing system health, configuration, and status	codesigning_admin, codesigning_manager, codesigning_auditor	Both
View signature verification status	View the status of valid, invalid, and orphan signatures across applications	codesigning_admin, codesigning_manager, codesigning_auditor	Both
View Key Pair and Certificates dashboard	Monitor certificate status, expiration dates, and validity for Code Signing certificates	codesigning_admin, codesigning_manager, codesigning_auditor	Both
View Code Signing configuration dashboard	Monitor system properties and key settings that control Code Signing	codesigning_admin, codesigning_manager, codesigning_auditor	Both
View MID Server configuration dashboard	Manage and configure trust relationships and certificate settings for MID Servers	codesigning_admin, codesigning_manager, codesigning_auditor	Both
Access Code Signing logs	Access logs to troubleshoot and identify Code Signing failure reasons	codesigning_admin, codesigning_manager, codesigning_auditor	Both
View Code Signing change audit data	View and report on create, update, and delete operations performed on records protected by Code Signing	codesigning_auditor	Protected

Code Signing change audit data

Review the create, update, and delete operations that users perform on records protected by Code Signing.

Code Signing records create, update, and delete operations on a protected record in the sn_cse_vault_codesigning_audit_data table. Use this audit data to identify who changed a protected record, which record they changed, and when the change occurred.

Audit data is written by the platform after Code Signing is activated on your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Operations that generate audit data

The platform writes an audit record only when all of the following conditions are true:

- Code Signing is activated on the instance. The *com.snc.kmf.signature.validation.optin* property is set to **true**.
- The *sn_cse.com.snc.csf.vault_audit_enabled* property is set to **true**. This property is set to **true** by default.
- The instance is a production instance. Development and test instances don't generate audit data.
- The record belongs to a table that has a Code Signing signature configuration. If the signature configuration includes a signature generation filter, the record must also match that filter.
- The table isn't listed in the *com.glide.codesigning.tables.excluded_from_audit* property. By default, this property excludes the internal tables that Code Signing uses for certificate storage, cryptographic module and policy configuration, and signing job tracking.

For descriptions of these properties, see Properties installed with Code Signing.

Audit record fields

Audit data table fields

Field	Description
Application scope (sys_scope)	Application scope that the changed record belongs to.
Package (sys_package)	Package that the changed record belongs to.
Document ID (document_id)	Sys ID of the changed record.
Table name (table_name)	Table that contains the changed record.
Modified by (modified_by)	User who performed the operation.
Modified on (modified_on)	Date and time when the operation occurred.
Operation (operation)	Type of operation: `create`, `update`, or `delete`. If the platform can't determine the operation type, the value is `unknown`.

Access to audit data

Users with the sn_cse.codesigning_auditor role can view the audit data and report on it. For more information about this role, see Code signing auditor [codesigning_auditor].

Create, update, and delete operations on the sn_cse_vault_codesigning_audit_data table are restricted to the platform. No role grants write access to this table.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Audit data retention

The *Vault Code Signing Audit Data Cleaner* scheduled job runs every 12 hours and removes audit records in two passes:

1. Deletes audit records that are older than the retention period set in the *sn_cse.com.snc.csf.vault_audit_data_retention_days* property. The default retention period is 90 days. Valid values are 30 through 360. If you set a value outside this range, the job uses the nearest limit and the property value remains unchanged.
2. Compares the remaining record count against the *sn_cse.com.snc.csf.vault_audit_data_max_size* property, which is set to 9,000 records by default. If the count is higher, the job deletes the oldest records until the count matches the configured maximum.

Only a user with the sn_cse.codesigning_admin role can change these properties. Export the audit data that you want to keep for longer than the retention period.

Note: Because the job enforces a maximum record count, it can delete older audit records before the retention period ends when the record count exceeds the configured maximum.

Troubleshooting and accessing logs

Access various logs to troubleshoot and identify the failure reasons.

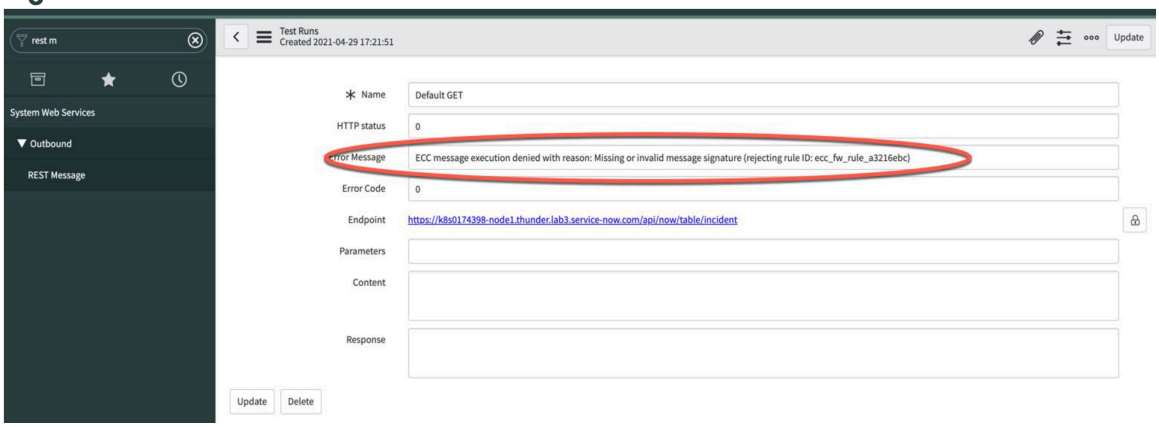
Code Signing logs

If any of the ECC queue records is not signed by the Code Signing Tracker API, the unsigned messages and the required details are displayed in the Code Signing module. Navigate to **System Logs** > **System Log** > **Code Signing** to access the list of records that are not trusted.

For additional debug node logs, enable *com.glide.codesigning.tracking.debug* and set its value to `true`.

Code Signing change audit data

To review the create, update, and delete operations that users performed on protected records, use the *sn_cse_vault_codesigning_audit_data* table. Each audit record identifies the changed record, the user who changed it, the operation type, and the date and time of the change. Users with the *sn_cse.codesigning_auditor* role can view this data.



Audit data is separate from the Code Signing system logs described in this topic. For details about the audit fields, the conditions that generate an audit record, and the retention behavior, see Code Signing change audit data.

REST message signature validation failure on MID Server

Access the error message regarding to the signature validation failure, by navigating to **System Web Services** > **Outbound** > **REST Message** and opening the required REST message record.

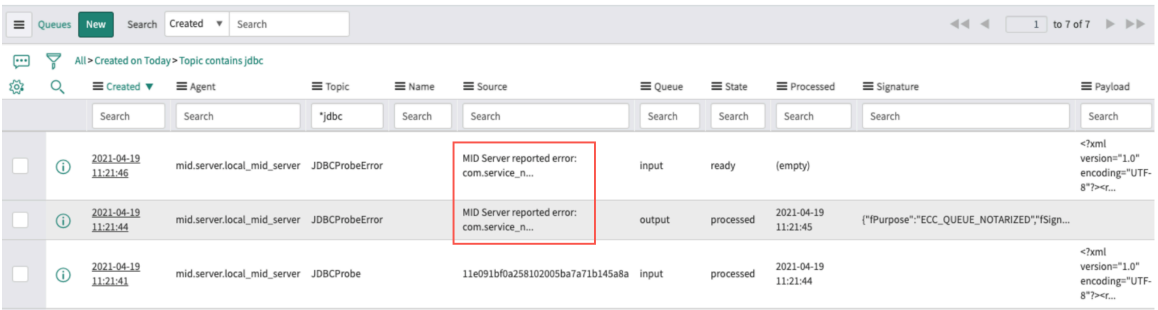
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Signature validation failure on MID Server

Note: Error messages related to the ECC firewall rejections start with ECC `message execution denied`.

ECC queue when signature validation fails on MID Server

Error message when ECC message is blocked by the user rule



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

JDBC probe

When a JDBC data source with an invalid or missing signature is executed on a MID Server, an error message with the required details is displayed.

Source also displays the details of the error message.

MID Server logs

To enable the detailed ECC firewall logging, increase the log level by setting the value of the MID Server configuration parameter, *`mid.log.level`*, to TRACE. The detailed logs provide information about:

- Rules that the MID Server loaded from the boot configuration file.
- Granular execution trace of rules.
- Specific rule due to which an ECC message is to be accepted or rejected.

Note: If `boot-config.xml` is invalid, the MID Server fails to start and the failure details are logged in the MID agent logs.

Reference for Antivirus scanning

Know about the Dictionary Attributes for Antivirus Scanning.

Exploring Antivirus Scanning

Use Antivirus Scanning to help protect your instance against virus infections that can be introduced by file attachments to your system records, such as incidents, problems, and stories.

Antivirus Scanning scans file attachments stored in your attachment [sys_attachment] table to help protect users from uploading and downloading infected files. All the document types supported by the Platform are scanned by Antivirus Scanning.

If Antivirus Scanning is enabled, all file attachments in the Attachments table [sys_attachment.do] are scanned by default.

The Antivirus Protection plugin (com.glide.snap) is activated and enabled by default on your instance. As an administrator, you can deactivate and reactivate the Antivirus Scanning feature across your instance at the switch of a toggle, set configuration options, and review antivirus activity on the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

- Antivirus Scanning is also available for customers in the Government Community Cloud (GCC) and commercial environment.

  GCC Users must set the (com.glide.snap.fed_enable_scan) property to `true` to start using the feature.

  Commercial users must set *com.glide.snap.enable_scan* to `true`.

- HTTP and HTTPS communication protocols are supported.
- Edge-encrypted files are excluded from this scan.
- Antivirus definitions are updated everyday.
- Any file above 100-MB file size isn't scanned.

Email scanning

Inbound emails are scanned for viruses by the system email filters, not by Antivirus Scanning.

File Attachment field in a table

The addition of a **File Attachment** field in a table generates zz_yy tables. These tables are dynamic and virtual. They are automatically generated when the column type **file_attachment** is added to parent tables.

Consider adding a user photo to the Users table and incorporating it into the form view. When a photo is uploaded to a record, it automatically uploads the attachment to the sys_attachment table. The sys_attachment table maps the photo to the zz_yyUsers table.

By default only attachments attached to zz_yylive_profile tables are scanned. To scan other tables that have column type **file_attachment** create the system property *com.glide.snap.scan.zz_yytables* and insert the table name.

Example

The "zz_yyincident" and "zz_yycase" tables are dynamic tables created when the column is added to the parent tables: Incident and Case, then the property value should be *zz_yyincident,zz_yycase*.

After this property is set, attachments for the zz_yyincident and zz_yycase tables are scanned.

Scanning scenarios

Review these upload and download scenarios to understand how the system identifies potential security threats from files attached to your records.

Scenario 1 - Upload a file

1. The user unknowingly uploads an infected file to a record.
2. The system scans the file and moves it to quarantine.
3. The file appears in the Attachments window, where it's marked as unavailable.
4. The user selects the file and this error message appears: `The file Infected_testing.txt did not pass the security scan. Please remove the file from record INC0000059 and try again.`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. The system sends an email notification to the user and the antivirus administrator.
6. The user closes the Attachments window and is returned to the record. The infected file is displays in the header as unavailable. Example, `infected_testing123.txtZ [unavailable]`.

Scenario 2 - Download a file

1. The user opens a record to download a file that is attached to it.
2. Unaware that the file is infected, the user selects it for download.
3. The system scans the file, moves it to quarantine, and displays a message similar to `The file infected_testing123.txt did not pass security scan and cannot be downloaded.`
4. The user closes the message and the screen refreshes showing that the file is unavailable.
5. The system sends an email notification to the user and the antivirus administrator.

Scenario 3 - Download a ZIP file

1. A user opens a record and downloads a ZIP file that is attached to it.
2. The system scans the ZIP files individually.
3. One file doesn't pass the security scan and is marked as unavailable. The remaining files are zipped and downloaded successfully.
4. The user opens the ZIP file and sees an "error.txt" file in addition to the successfully downloaded file. This file contains an error message specifying which file didn't pass scanning and was therefore not included in the ZIP.
5. The user opens the record again, and sees that the unavailable file has been moved into the **Potential security risks** section in the Attachments window and can't be downloaded.

Configuring Antivirus Scanning

Configure Antivirus Scanning across your instance and at the table level.

Before you begin

Role required: antivirus_admin or admin

About this task

Antivirus Scanning is active by default in your instance, where it automatically scans attachments to identify any files that are infected by viruses. Configure the feature by ensuring the scan is enabled across your instance, and by identifying any tables that you want to exclude from the scan.

Procedure

1. Navigate to **All** > **Antivirus** > **Configuration**.
2. As you configure the feature, consider the following.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Description
Enable Antivirus scanning	Antivirus scanning is active and enabled on the instance by default, its toggle is set to the on position and appears green. **Note:** To set the property to be `false` contact customer support.
Allow attachments to be downloaded when Antivirus scanner is unavailable	If this option is set to the on position, antivirus scanning is bypassed if the scanner times out, and a response can't be obtained. In this situation, the file download proceeds without completing the scan. If the option is set to off, the file download is prohibited until the scan can complete successfully.
List of Tables Excluded	Any file attachments associated with a table in this list are excluded from antivirus scan ning. Proceed to Step 4 if you want to define the tables the system excludes from scan ning.

3. Select **Save**.
4. Exclude tables from the Antivirus scan by adding them to the **List of Tables Excluded**.
   a. Navigate to **System Definition** → **Dictionary**
   b. Search for the table you want to exclude from the scan and select the table with Type set to collection.
   c. In the **Attributes** tab, select **New**.
   d. Add `Exclude_from_antivirus_scan` in the Attributes field and enter `True` in the **Value** field.
   e. Select **Submit**.

Result
Antivirus Scanning is enabled in your instance, and the **List of Tables Excluded** on the Antivirus Configuration page is populated with all the tables that you excluded from the scan.

Reviewing quarantined files

Review quarantined file attachments and take further action as needed.

Before you begin
Role required: antivirus_admin or admin

About this task
Monitor your quarantined file entries in the Antivirus Quarantine page at regular intervals to perform any of the following actions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Antivirus** > **Quarantine**.
2. Select the check box next to each quarantined entry on which you want to perform an available action.
3. Select the **Actions on selected rows** drop-down in the banner to choose the action to be performed on the selected row quarantined entry.

Action	Description
Delete	Select this action to delete the quarantined file if it is not required any more by users.
Restore	Select this action to restore the file based on your assessment of its status or on the user request. However, scan the file with your third-party antivirus product before you re store it to mitigate any virus threats. Once re stored, the file is available for download to the user.
Download	Select this action to download the file to your local system for further scanning and analy sis.

Result
The system asks for confirmation and performs the selected action per your input.

Related topics

Review antivirus activity

Review the Antivirus Activities log that tracks all activities that occur on potentially-infected files from the point that they are discovered and placed into quarantine.

Before you begin
Role required: antivirus_admin or admin

About this task
This log functions as a report that captures antivirus activity, such as discovery, deletion, and other possible quarantined file events.

Procedure

1. Navigate to **All** > **Antivirus** > **Activity**.
2. Review the log of quarantined files.
   You can view the actions performed in the Event column for each quarantined file.

What to do next
Determine which records you want to delete, restore, download, or keep in the log. See Review quarantined files

Understanding Dictionary attributes for Antivirus Scanning

Dictionary attributes alter the behavior of the table or element that the dictionary record describes. As an administrator, you can set the values of dictionary attributes to modify the behavior of the default Antivirus Scanning configuration.

Dictionary attributes for Antivirus Scanning

Name	Value	Target element	Description
Exclude_from_antivirus_scan	true/false	any table	If true, file attachments on the table are excluded from the antivirus scan. See Configuring Antivirus Scanning
Supress_antivirus_email_notification	true/false	any table	If true, stops sending Platform-generated email notifications when a potentiality-infected file is identified.
Suppress_antivirus_ui_notification	true/false	any table	If true, stops Platform-generated UI notifications when a potentially-infected file is identified.

Configure HTML Sanitizer

Configure the HTML sanitizer.

Activate HTML Sanitizer

Learn how to enable the HTML sanitizer.

Exploring HTML sanitizer

Remove unwanted code and protect against security concerns such as cross-site scripting attacks by sanitizing HTML markup in HTML fields and translated HTML fields.

Use HTML sanitization to ensure HTML content within your instance doesn't contain potentially harmful content. HTML sanitization works by removing HTML tags that could be used to compromise your instance, such as `<script>`, `<link>`, or `<embed>` tags that can be used to run unwanted scripts on your instance or direct your users to unwanted content. Safe tags that control the formatting of your content are preserved. As an administrator, you're able to customize what content is removed or preserved. You're also able to control whether sanitization applies to all content, or just fields you specify.

The HTML sanitizer works by checking the built-in inclusion list for markup that you always want to preserve. The sanitizer provides the *HTMLSanitizerConfig* script include that administrators can use to modify the built-in inclusion list. Items can also be added to the exclusion list to remove HTML markup. Contents of the exclusion list override the inclusion list.

The following types of items can be added to the inclusion and exclusion lists:

- Global attributes
- Any HTML elements

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note: By default, URL attributes like `href` and `src` support only these protocols:

- `http`
- `https`
- `mailto`
- `data`

For example:

```
<a href="https://community.servicenow.com/community">ServiceNow
Community</a>
```

Note: To learn more about the *`glide.html.sanitize_all_fields`* property that controls use of the HTML sanitizer, see Enable HTML Sanitizer [Updated in Security Center 1.3] in Instance Security Hardening Settings.

Configure urlAttributes and the protocols

You can configure urlAttributes and their protocols in the **HTMLSanitizerConfig** script include. In the script include, `HTML_WHITELIST` configures the inclusion list and `HTML_BLACKLIST` configures the exclusion list. For example:

```
HTML_WHITELIST : {
urlAttributes: { "protocols" : [ "file", "notes" ] },
                 -   -
                 -   -
        }
```

Because `notes` is in the inclusion list in this example, this URL isn't sanitized:

```
<a title="Lotus"
 href="Notes://
ABC/X575C90019DE33/ABC594DCB76D86EB4925653E0011C4C1/ZZ90B7E2D339
64749257EEA003456FD">Lotus</a></p>
```

Default Inclusion List

Note: The Default Inclusion List is a system list and is not accessible by users in the Instance.

```
BUILTIN_HTML_WHITELIST :{

 globalAttributes:{ attribute:["id","class","lang","title","styl
e"],

                                attributeValuePattern:{}},

Using variables and templates in HTML fields

HTML/Translated HTML fields undergo HTML sanitization by default. This process sanitizes the input HTML to protect it from cross-site scripting (XSS) and related security attacks. Storing

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

templates or variables such as ${description} or {{description}} or similar and replacing them with a true description post sanitization will reduce the effectiveness of the sanitization process. This is due to the sanitization being called solely on the placeholder template and not the HTML content. Storing only HTML content in the HTML/Translated HTML fields helps ensure an effective sanitization process.

Configuring HTML sanitizer

You must modify a script include to make configuration changes to the HTML sanitizer.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **System Definition** > **Script Includes**.
2. Open **HTMLSanitizerConfig**.
3. To add items to the exclusion list, use the HTML_BLACKLIST class.

   To add items to the inclusion list, use the HTML_WHITELIST class.

   Use this format:

```
HTML_XXXXLIST :{
        globalAttributes :{

            attribute:[attribute-name1,...],

 attributeValuePattern:{ attribute-name2:attribute-value-reg
ex-pattern,...}

        },<html-element-name>:{// Same as Above},----}
```

   - *globalAttributes* contains attribute or attributeValuePattern items that are applicable globally for all the HTML elements.
   - *attribute* is a comma-separated list of attributes.
   - *attributeValuePattern* is a dictionary of attribute to attribute-value-regex-pattern pairs. The attribute-value-regex-pattern is a regular expression which has to match the attribute value.

Example:
Consider the following example:

```
HTML_WHITELIST:{
        globalAttributes:{
            attribute:["id","name"],},
        img:{
            attribute:["style","align"],
            attributeValuePattern:{src:".*jpeg"}},
        iframe:{},}
```

It adds the following items to the inclusion list:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- The global attributes id and name. This is a list of strings that can be applied globally to all the elements.
- The img element where the attributes are style and align.
- The img element where the source attribute of the image is a file with the .jpeg extension. This is an example of a regular expression pattern that matches an attribute value.
- The iframe element.

Enabling HTML sanitizer

The HTML sanitizer provides a property to enable or disable the sanitizer for all HTML fields in the system.

Before you begin
Role required: admin

About this task
By default, the property is set to true for new instances.

Procedure

1. In the navigation filter, enter `sys_properties.list`.
2. Set the properties *`glide.html.sanitize_all_fields`* and *`glide.translated_html.sanitize_all_fields`* to **true**.

   Note: To learn more about this property, see Enable HTML Sanitizer [Updated in Security Center 1.3] in Instance Security Hardening Settings.

Trouble?

If the properties do not exist in the System Properties table, you can add them.

Enable sanitization on individual fields

You can use field attributes to enable or disable the sanitizer on individual fields.

Before you begin
Role required: admin

About this task
You need to first set the sanitizer property to false, and then enable the sanitizer on a per-field basis for any form.

Procedure

1. Navigate to the sys_properties table and set the *`glide.html.sanitize_all_fields`* to **false**.
   This disables the sanitizer for all HTML fields in the system.
2. Navigate to the form that contains the HTML field.
3. Right-click the HTML field label, and select **Configure Dictionary**.
   The Dictionary Entry form opens for the HTML field.
4. Enter one of the following in the Attributes field:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- To disable sanitization enter `html_sanitize=false`
- To enable sanitization enter `html_sanitize=true`

5. Click **Update**.
6. To enable the HTML sanitizer for translated HTML fields, set the *`glide.translated_html.sanitize_all_fields`* property is **true**.

Enable HTML Sanitizer logging

When the HTML sanitizer removes elements or attributes, they are added to the system log.

Before you begin

Role required: admin

About this task

You can review these sanitized elements by adding /syslog_list.do?sysparm_query=source %3DHTMLSanitizer to your instance URL.

Procedure

1. To review these sanitized elements add `/syslog_list.do?sysparm_query=source %3DHTMLSanitizer` to your instance URL.
2. To enable or disable logging, add the `glide.html_sanitize.discarded_log.enable` property to the system properties and set the value to **true** (enabled) or **false** (disabled).
   This property is **true** by default.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Auditing

Track record changes on auditing-enabled tables. By default, the system tracks changes to the incident, change, and problem tables, among others.

Explore

Learn the features and business values of Auditing.

Configure

Understand how to configure Auditing.

View

Review the Sys Audit and Audit Relationship Change tables.

Reference

Know about the History sets.

Exploring Auditing

Track record changes on auditing-enabled tables. By default, the system tracks changes to the incident, change, and problem tables, among others.

Enabling auditing tracks the creation, update, and deletion of all records in the table. If you want to audit individual fields in a table, you can hide fields you don't want to track using a dictionary attribute.

Auditing information is kept in these tables:

- The Audit table.
- The Knowing about History sets table.

Warning: Auditing system tables that receive a large amount of traffic, such as workflow Contexts [wf_context] or Event Management Alerts [em_alert], can impact performance. For this reason, you can't audit the em_alert table as a whole. Instead, audit selected fields of interest. Set `audit=true` on both the em_alert table and the selected fields. Try to audit as few fields as possible.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Auditing parent and child tables

Tables don't derive the audit flags from parent or child audited tables.

- For example, if you enable auditing for the Configuration Items [cmdb_ci] table, only CIs stored in that base table are audited.
- Likewise, if you enable auditing for the Computers [cmdb_ci_computer] table, only the computer CI records are audited, including any fields on the Computers [cmdb_ci_computer] table that is derived from the Configuration Items [cmdb_ci] table.

Auditing system tables

By default, the system doesn't audit the deletion of a record from system tables. To audit a system table, add it to the list of tables in the *glide.ui.audit_deleted_tables* property list.

Auditing deletions from a form or list

By default, the system audits deletions of individual records from a form. To prevent auditing, set the table's dictionary attribute *no_audit_delete*.

The system audits deletions from a list when it **audit** is selected on the table dictionary, and the table isn't listed in the *glide.db.audit.ignore.delete* property.

Note: By default, the *glide.db.audit.ignore.delete* property isn't present in the System Property [sys_properties] table. To change the property, and its associated values, you must first manually add it. However, when manually added, it overwrites the following default values:

```
glide.db.audit.ignore.delete =
sys_mutex,sys_db_cache,sys_lucene_block,sys_lucene_file,sys_lucene_directo
cmdb_ci_windows_service, cmdb_sam_sw_install,
cmdb_software_instance, cmdb_sam_sw_usage,
sam_sw_counter_detail
```

To learn more about adding system properties, see Add a system property

It is to be noted that by default, the audit deletes are enabled whether the record is deleted from the form view, list view, or through a script/scheduled job.

Information audited

Auditing tracks the following record changes:

- Unique Record Identifier (sys_id) of the record that changed
- Field that changed
- New field value
- Old field value
- Number of times this record and field have been updated
- Date and time when the change occurred
- User who made the change
- Reason for the change (if any reason is associated with the change)
- Internal checkpoint ID for the record, if the record has multiple versions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Information exempted from auditing

Some updates aren't audited despite enabling auditing on a table. For example, you may see 132 updates in a record's history, but only seven audited ones.

Auditing excludes the following information:

- Updates made by an upgrade.
- Updates are made through import sets.
- Records in parent or child tables.
- Fields with the no_audit dictionary attribute.
- System tables are not listed in the *glide.ui.audit_deleted_tables* property list.
- Fields that begin with the sys_ prefix (system fields), except the sys_class_name and sys_domain_id columns.
- UI Pages can sometimes trigger updates to a record without creating an audit log.
- Anytime an inactivity monitor touches a record. It prevents you seeing possibly hundreds of updates listed against an incident, with the noise drowning out the useful data.
- Manual changes to Performance Analytics scores.
- Applying Update Set
- Import XML

Auditing a table

For instructions on how to audit a table, see Configuring auditing for a table.

By default, the system tracks all fields in an audited table. You can audit a subset of fields in a table in one of two ways:

- You can enable auditing for the entire table, then exclude those fields you don't want to include. It's appropriate when you want to audit most, but not all, fields, and is referred to as an exclusion listing. For more information, see Exclude a field from being audited (exclusion listing).
- You can enable auditing for the table, but only for specified fields. It's appropriate when you want to audit only a small number of the table's fields and is referred to as an inclusion listing. For information on how to include a field using an inclusion listing, see Include a table field in auditing (inclusion listing).

Non-cancellable audit records

Reduce the chances of audit records not being recorded when a transaction is canceled with the new default setting.

Audits have been set to create a record immediately in the same transaction with the target record write operations. If the target record gets deleted, the audit still gets created and retained under **NCA Test Audit Delete** module.

Note: The enhanced audit process is enabled by default. If the `glide.db.audit.lazy` property is set to `True`, the enhanced audit process is disabled.

Prior to Brazil release, if a transaction is cancelled, certain auditable operations were missed being recorded. This is because the platform executes some operations between the record change and is cancelled before audit creation. But, now audits are created immediately after the record is changed, reducing the chances of a cancelled transaction aborting the operation before the audit is recorded.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Audits are now recorded in the same thread as the transaction. Earlier audits were created in a background thread. This change redefines the default value of the `glide.db.audit.lazy` property from True to False. This property is not usually defined in the Properties table because the majority of instances start using the new default value and behavior. On some instances, this property might be already present and set as True, which means that these instances won't be able to use this change to audit behavior.

Note: It is recommended to delete this property to leverage the update.

Configuring auditing for a table

You can enable table auditing to track changes to all or some of the table's fields.

Before you begin

Role required: admin.

Note: Encrypted fields aren't audited by design. This behavior isn't configurable.

Procedure

1. Navigate to **All** > **System Definition** > **Dictionary**.
   The system displays the list of dictionary entries. The list includes a row for each table as well as a row for each column (field) in the table.
2. In the list of dictionary entries, find the row corresponding to the table you want to audit, for example `cmdb_ci_computer`.
   You can distinguish the row for the table itself – versus a row for a column in the table – by finding the row with the correct table name, an empty entry for the **Column** name, and a **Type** of **Collection**.
3. Select the dictionary entry for the table.
   The system displays the dictionary entry form.
4. Check the **Audit** check box.
5. Select **Update**.

What to do next

If you want to audit only a few fields in the table Enable inclusion list auditing for a table. If you want to audit most – but exclude some – fields, see Exclude a field from being audited (exclusion listing).

Enable inclusion list auditing for a table

Enable a table to audit only those fields you explicitly designate. This is useful when you want to audit only a small number of fields in an audited table.

Before you begin

Role required: admin
The table must be enabled for auditing.

Procedure

1. Navigate to **All** > **System Definition** > **Dictionary**.
   The system displays the list of dictionary entries. The list includes a row for each table as well as a row for each column (field) in the table.
2. If necessary, customize the list view to show the **Attributes** column.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. In the list of dictionary entries, find the row corresponding to the table you want to audit, for example `cmdb_ci_computer`.
   You can distinguish the row for the table itself – versus a row for a column in the table – by finding the row with the correct table name, an empty entry for Column name, and a type of *`collection`*.
4. In the **Attributes** field for that row, enter *`audit_type=whitelist`*.

What to do next
Designate which fields you want to audit in this table.

Enable impersonation tracking in audit logs

Track users who perform actions through impersonation in audit logs.

Before you begin
Role required: admin

Procedure
1. In the filter navigator, enter `sys_properties.list`.
2. Select **New** on the form header.
3. In the **Name** field, enter `glide.audit.track_impersonation`.
4. In the **Value** field, enter `true`.
5. Select **Submit**.

Result
Impersonation tracking is enabled. The Sys Audits [sys_audit] table will record both the impersonated user and the user ID of the user who actually performed the actions.

What to do next
For information about converting the user ID to the actual user name, see Map user IDs to user names in audit records.

Exclude a field from being audited (exclusion listing)

Prevent the ServiceNow AI Platform from tracking a subset of fields in an audited table by excluding those fields from an audit.

Before you begin
Role required: admin
To exclude a field in a table from being audited, you must have first enable auditing for that table.

About this task
Add a set of fields to an exclusion list when you want to audit most of the fields in an auditable table. If you want to audit only a few fields, follow the inclusion listing procedure instead.

Note: Disabling auditing on journal-based fields can impact the functionality of features, such as the Activity Formatter.

Procedure
1. Navigate to **All** > **System Definition** > **Dictionary**.
2. If necessary, customize the list view to show the **Attributes** column.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. Navigate to the row corresponding to the table and field (column) you want to exclude from auditing.
4. In the **Attributes** column for that row, enter `no_audit`.

Include a table field in auditing (inclusion listing)

Track a subset of fields in an audited table by add those fields to an inclusion listing.

Before you begin

Role required: admin
To add fields in a table to an inclusion list, you must have first enabled auditing for that table and enabled inclusion list auditing for that table.

About this task

Add a set of fields to an inclusion list when you want to audit only a small number of an audited table's fields. If you need to audit most fields, and exclude only a few, follow the exclusion list procedure instead.

Procedure

1. Navigate to **All** > **System Definition** > **Dictionary**.
2. If necessary, customize the list view to include showing the **Attributes** column.
3. Navigate to the table and field (column) you want to the inclusion list.
4. In the **Attributes** field, enter *`audit=true`*.

Enable auditing for a system table

Deletions from tables with a sys_ prefix are not audited by default. To track deletions from these tables, add the table name to the *`glide.ui.audit_deleted_tables`* property. Enabling the Restore Deleted Records plugin adds several default values to this property.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Properties** > **UI Properties**.
2. Locate the **List of system tables (beginning with "sys_", comma separated) that will have the delete audited** property.
3. Add or remove table names. Table names should be separated by commas, without any spaces.
4. Click **Save**.

Note: For more information about auditing, see Understanding the sys audit Table.

Configure auditing using Audit Management Console

Use Audit Management Console module to experience a more enhanced way of defining and configuring the audit capability within your instance.

Before you begin

Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Audit Management Console**.
   A list of all tables in your instance shows up.

   Note: By default, the list of tables that has set Audit enabled shows up.

   You can select **Disabled** tab to see the list of tables that has set Audit disabled. You can also select the All tab to see all the tables in your instance with either enabled or disabled Audit option.

2. Select the table from the list you want to update the auditing configurations.
   The table with its respective columns show up. You can also see the total number of columns in the selected table.

   Note: **Columns** and **Retention** are the tabs that show up on the table.

3. Modify the Audit toggle depending on if you want to enable or disable audit for the selected table.

   Note: When Audit is enabled in a table, all the columns and fields within the table are enabled by default.

4. **Optional:** Select **Edit Audit Status** if you don't want all the columns to be enabled within an audit enabled table.
   The Select Columns to be Edited modal shows up.
5. **Optional:** Unselect the columns that you don't want to be enabled.
   You can also add any column by checking the column from the Available columns list.
6. Select **Save** to save the latest modifications.
   Select **Clear All** to remove all the columns being enabled. See Setup your audit retention for more information about audit data retention.

Setup your audit retention

Use the Retention option to automate and simplify the deletion of audit data as per your requirement.

Before you begin

Role required: security_admin

Procedure

1. Navigate to **All** > **Audit Management Console**.
2. Select the table from the list you want to update the retention policy.

   Note: By default, you land on the Columns tab at the end of this step.

3. Select the Retention tab to update the retention policy for the selected table audit data.
   A modal showing the retention option shows up.
4. Enable the Automatically Purge Audit Records toggle.
5. Select the duration from the Duration dropdown menu.
   Select **Yes** if you want to proceed with the selected duration. You can also select **Cancel** if you want to select a different duration.

   Note: Logs older than your set duration will be purged and can't be restored.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The Retention Policy modal shows up confirming the selected duration.

6. Select **Generate Estimate** to view the approximate number of audit records that are older than your selected duration.
   For information about generate estimate, see Enable an audit deletion estimate
7. Select **Save** to update the retention policy for the selected table.
8. **Optional:** To disable deletion of Audit records of a table, disable the Automatically Purge Audit Records toggle and select **Save**.

Note: The audit records that were previously deleted due to the selected retention duration are permanently unavailable.

Enable an audit deletion estimate

Enable the audit deletion estimation feature that calculates the approximate number of records that will be deleted based on retention policies. This information helps you make an informed decision before applying a retention policy, which permanently deletes audit data and cannot be reversed.

Before you begin
Role required: admin

Procedure

1. In the filter navigator, enter `sys_properties.list`.
2. Set the relevant system properties.

Name	Value
com.glide.stats.table_stats.data_source	information_schema
com.glide.stats.storage_disk_usage.information_schema	true

3. Select **Submit**.

Result
The estimated number of records to be deleted appears in the **Retention** tab of the Audit Management Console.

Viewing Sys Audit and Audit Relationship Change tables

The ServiceNow AI Platform tracks inserts and updates to audited records in the Sys Audit (sys_audit) and Audit Relationship Change (sys_audit_relation) tables.

The ServiceNow AI Platform tracks audit tables. To track tables, select the **Audit** check box in the dictionary record to set the value to true. By default, it does not audit records from system tables, such as update sets tables.

Note: To prevent performance issues and infinite loops, the system skips any business rule or workflow triggered by inserts to the Sys Audit table.

Sys audit table columns

Access the Sys Audit table on your instance by entering `sys_audit.list` in the navigation filter.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The following columns appear in the sys_audit table records:

Field	Description
Table name	Table that the audit record is for (for example, "`incident`")
Field name	Column in the table that the audit record is for (for example, "`assigned_to`")
Document key	Sys_id (Unique Record Identifier) for the originating record associated with the audit record.
User	Name of the user who created the change. **Note:** Some automated processes use the system or guest user to apply and track changes to records. For more information, see System and guest users.
Old value	Old value of the field change represented by this sys_audit record. • Reference fields: Unique sys_id value of the changed record. • Date and time fields: Value in Coordinated Universal Time (UTC) as stored in the database.
New value	New value of the field change represented by this sys_audit record. • Reference fields: Unique sys_id value of the changed record. • Date and time fields: Value in Coordinated Universal Time (UTC) as stored in the database.

How the Audit Relationship Change (sys_audit_relation) table works

The Sys Audit [sys_audit] table tracks changes to reference fields in tables that are flagged for auditing. This activity includes journal field entries and history sets. The Audit Relationship Change [sys_audit_relation] table tracks relationship changes between sys_audit table records and the source tables that the audited records originate from. It also tracks when a record might have been deleted.

-
- Whenever you audit any record in a table, a relationship is created between the various originating tables to the store that records data. This relationship information is saved in the sys_history_set, sys_history_line, and sys_journal tables.
- If you delete a field that is related to an audited table record, the sys_audit_relation table records the deletion. In other words, anytime you change an audited record, it first deletes past elements, and then creates a relationship in the sys_audit_relation table with new document IDs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Knowing about History sets

The system automatically generates History Set records as needed from the Audit table when a user either creates a record or views its history.

If a record is in an audited table, its history set is generated when the record is inserted or when a user views the record.

Note: Don't use history sets to generate reports.

Several fields of information are captured in the History Set record, displayed in the list view.

List View Record Fields

Field	Input Value
ID	Document ID for the record whose history is being recorded.
Table	Audited table for the record whose history is being recorded.
Load Time	Amount of time it took to generate the history set.

Audit History Record Fields

Field	Input Value
Label	The label of the field that was changed.
Old	Value before the change.
New	Value after the change.
Type	Indicates if the entry is for a normal field, an email record, or a relationship change record.
Update Number	The number of times this field has been changed. A value of -1 indicates when the record was created or deleted.
Update Time	Date and time of the change. **Note:** The Update time for auto-generated history lines doesn't match the Created or the Updated time for a record in a specific processing situation. When you view a history set of a record for the first time, an initial set of history line records is auto-generated. Since file changes in an upgrade aren't audited, this date mismatch occurs when: • You view a history set after a change is made to a record, but • Before another change is made to it in a future upgrade.
User Name	Name of the user who created the change.

History Sets in a Calendar View

After History Sets are active, the History context menu choice populates using information from the history set, rather than from the `sys_audit` table. From the user's perspective, the same historical data is available in the same user interface, but how the information is stored is different.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Since the History view includes a calendar view, but doesn't use the normal list interface to filter and interact with the history records, it enables:

- Searching and filtering historic data.
- Exporting historic data.

Viewing history sets

There are two ways of viewing the history set, accessible through the Context Menu action **History**.

Differences Between Audit and History Sets

The Audit [sys_audit], History Sets [sys_history_set], and History [sys_history_line] tables store the same data, but they serve different purposes and manage data differently.

Audit [sys_audit] table

The Audit [sys_audit] table is where the system stores historical information for all records. These records are intended to be kept forever so that administrators can always track the history of audited records. As the number of auditing records grows over time, it becomes more inefficient to directly query the Audit table for historical information. It is much more efficient to run queries only on the smaller subset records you actually want to view historical information for.

History Set [sys_history_set] table

The History Set [sys_history_set] table identifies which particular records from an audited table have historical information. The History [sys_history_line] table stores the actual changes to field values that occurred.

- The system automatically generates History Set and History records as needed from the Audit table when a user either creates a record or requests its history.
- Rather than containing a complete history of all changes in the system, History Set and History records only contain a recent subset of historical information for records where users have created or requested such information.
- In addition to audit data, history sets also include the information that is set during record insert, including journal field entries. Journal field entries you create before creating a record are handled in the same manner as journal entries created at the time of record creation. These journal entries appear in history sets with the same creation time and created by data as the associated record itself.

The system limits History Set and History records by:

- Having the table cleaner delete History Set records that have not been updated in 30 days.
- Using table rotation to rotate between four History tables every seven days. Because the platform truncates the leading table when rotation occurs, the maximum available retention period is 21 days, not 28. One of the four tables is always in the process of being cleared in preparation for the next rotation.

Should someone need historical information again at a later date, the system can regenerate it from auditing source records.

After the system generates History Set records, the context menu choice **History** uses the History Set rather than Audit records. From the user's perspective, the same historical data is available in the same user interface, but the way the information is stored is different.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Control access to history

You can give a role access to view audit history by setting a system property.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **System Properties** > **System**.
2. Select the *glide.history.role* property from the table.
3. In the *List of roles (comma-separated) that can access the history of a record*, select the user roles you want to access history.
4. Select **Save**.

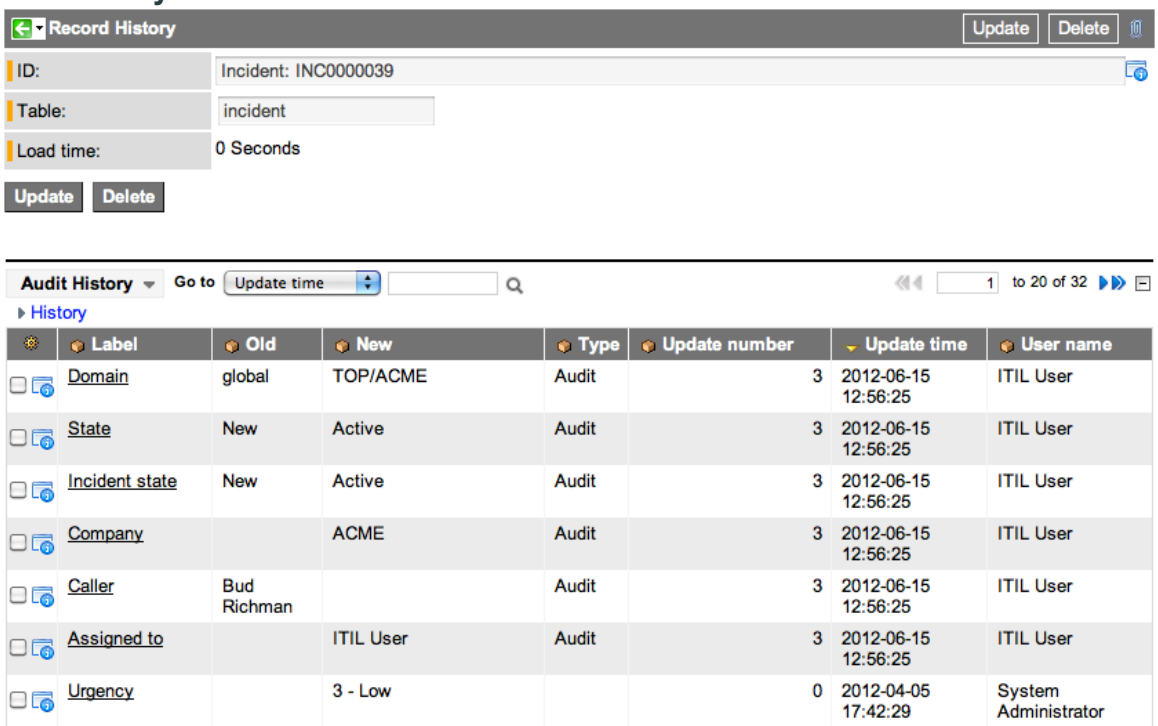
Result
Any changes to a field are omitted if a user without read-access views the history of a record.

Change the number of history entries

By default, the history displays a maximum of 250 history entries, but you can change this value.

Before you begin
Role required: admin

Procedure



1. Navigate to **All** > **System Properties** > **System**.
2. Select the *glide.history.max_entries* property.
3. Set the *Maximum number of field entries displayed in record history, default is 250* value with a new maximum number of entries to be displayed.

History List

The history list displays each change as its own row in the change list.

Click on a row item to view additional details about the change.

View List Change

Requirements

To view a history list, the following requirements must be met.

Auditing

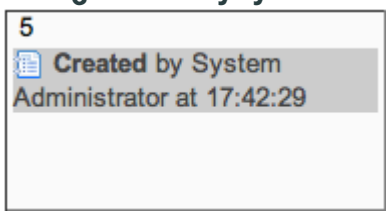
Auditing for the table must be enabled to view a history list.

ACLs

By default, the *List* history option is only available to users with the admin user role. To enable this option to non-admins, create a custom ACL rule granting read access to the Record History [sys_history_set] table.

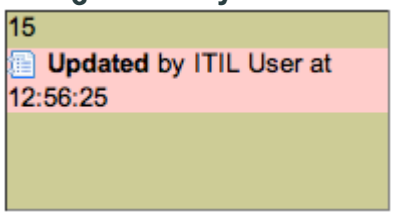
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Roles



At least one of the roles that the user has must be included in the *glide.history.role* property, which includes the itil role by default.

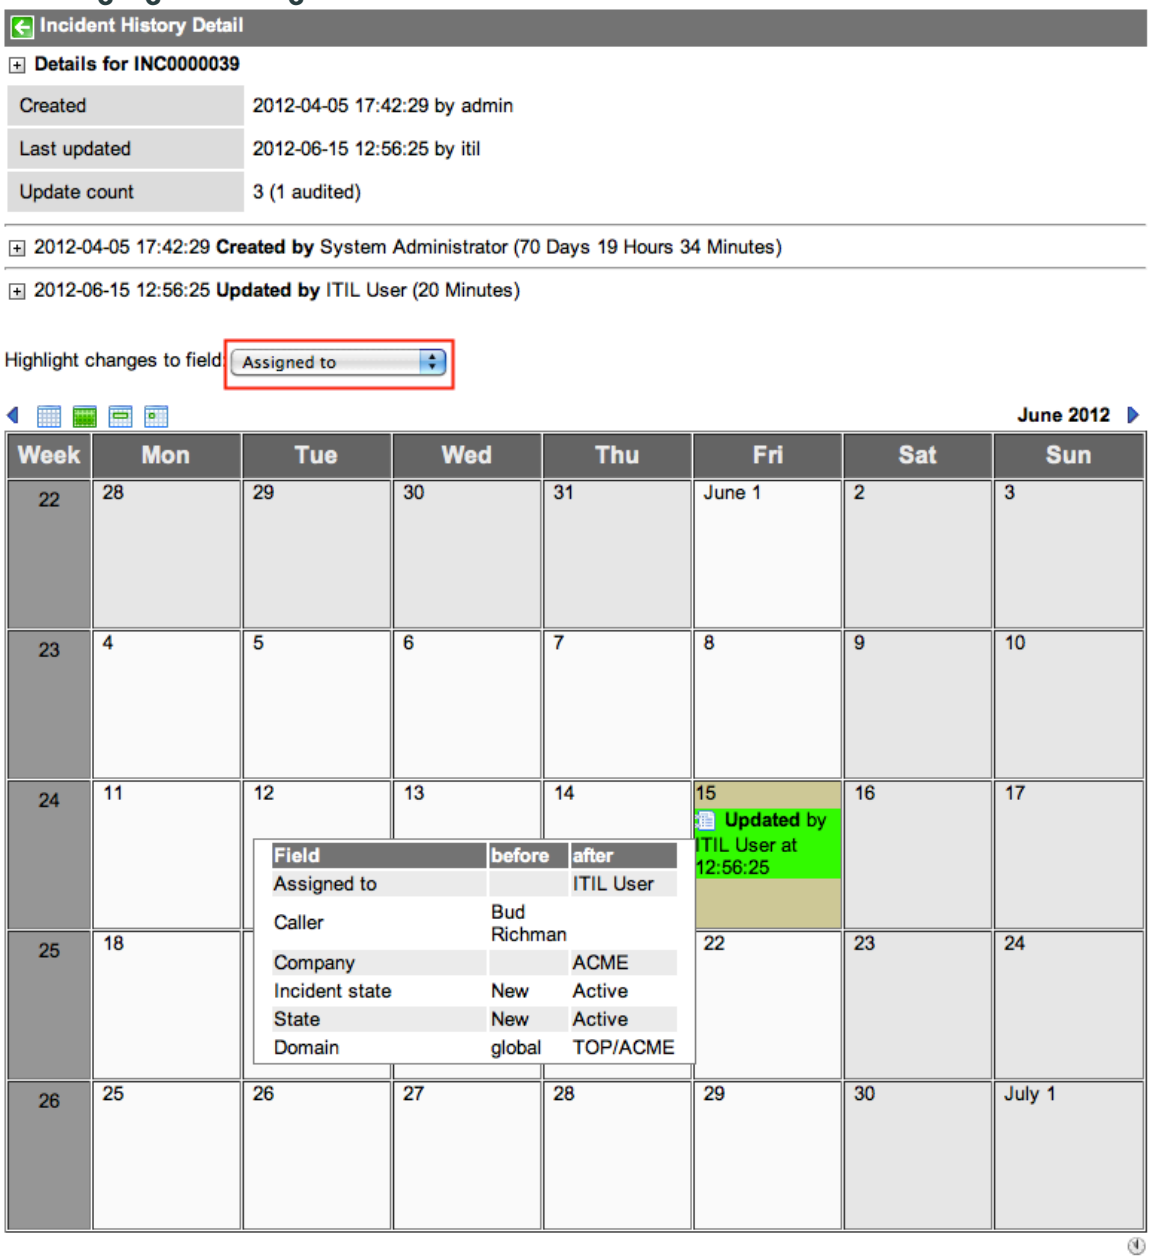
History Calendar



The history calendar shows you the days where the record was changed, who made the change, and when.

The History Calendar is sorted by update number. Each user is assigned a color so you can tell at a glance how many times a record was changed by a specific user. For example:

Changes made by system administrator



Changes made by ITIL user

To highlight changes to a particular field, select the field from the **Highlight changes to field** selection box. Picking a field from this selection box changes the calendar to highlight the times that field was changed. Hover over the text of one of a highlighted change to see the change in value.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

View highlighted changes

If you hover over the icon within an entry, a popup displays all the value changes. This is the same information that is displayed in the top part of the form.

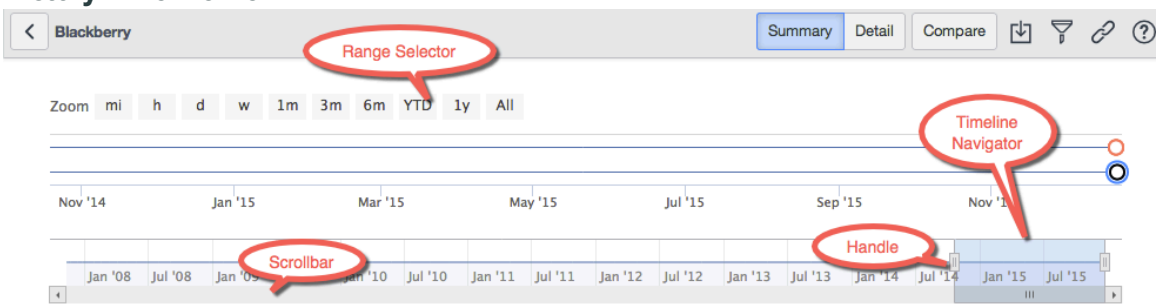
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You can click on the day number to get a view of the changes for that day. You can also click on the week number to the left to get a the week view. You can scroll to and from month to month to see changes.

History Timeline

You can view a timeline of changes for a CI and for its related records, relationships, baselines, and proposed changes for the CI. Timelines are available for CIs in the Configuration Item [cmdb_ci] table or a descendant of this table, if auditing is enabled for the tables.

Role required: The ACL for this view is based on the roles defined in the *`glide.history.role`* system property, which by default is set to `itil`. Also, the user must have read access to the History Set [sys_history_set] table, which by default is granted to admin.



You can open a timeline when you view the history of a CI. You can specify the time period, time range, and properties that are displayed in the timeline. You can view either what has changed in a particular change set, or view the entire CI to better troubleshoot any issues. You can also display a timeline of changes to the CI's related records, and export and compare snapshots of the CI at any point in time.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

CI changes are represented by bubbles in different shapes and colors along the timeline. The shape of each bubble represents a different type of change and the color of each bubble specifies whether the change is valid or invalid. CI baselines are represented by black circles that you can hover over to display more details. Click the **?** icon to display bubble shape and color definitions, and point to a bubble to display details about the change set.

A change to a relationship is considered valid only if it was applied through change management. If the change was applied via the Proposed Changes framework, it is valid. For additional validation steps, see Create or edit a planned validation script .

History Timeline view

Timeline bubbles

Note: Proposed changes that do not have a planned start date are placed at future points of time.

Timeline navigator

Use the handles on both ends of the timeline navigator to extend or to shorten the time period that is shown.

You can scroll to a different period of time by clicking on the bottom part of the timeline navigator and then dragging the navigator to the left or right.

Zoom

By default, the timeline for the last month is shown. Next to the **Zoom** label above the timeline, you can select another time interval. You can select intervals from a minute to the entire period of data.

If there are many changes of the CI during the time period, the bubbles displayed might get too crowded. You can zoom in or out to spread the bubbles in either method:

- Change the time interval on the timeline. As you shorten the time interval, you zoom in, and as you lengthen the time interval, you zoom out.
- Select the section of the timeline that you want to zoom into.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property filter

You can filter the bubbles that are displayed. By default, all bubbles are displayed, representing changes to all of the CI's properties. You can limit the view to display only the bubbles in which selected properties have changed and exclude bubbles in which only unselected properties changed.

The **Detail** and **Summary** views highlight properties within your filter scope that have changed. The changed properties are highlighted in light blue.

In the **Summary** view, you can choose to include all the properties of the CI, or only properties that have changed. If you choose to display all properties in the summary view, then changed properties are listed before unchanged properties.

Summary view

The **Summary** view displays snapshots of the CI's represented by each bubble. Each snapshot displays the changes to the CI's fields and relationships according to the change set. It displays old and new values before and after the change, and any relationships that were added or deleted.

Use the **>** and **<** buttons on both sides of the snapshot display to scroll through the next and previous change set records in a chronological order.

Detail view

The **Detail** view displays snapshots of the CI that correspond with the bubbles. Each snapshot includes the fields that are within the property filter scope, displaying the properties that have changed with a light blue background. Click on a bubble to display its corresponding snapshot of the CI. The data that is displayed is read-only.

Use the **>** and **<** buttons on both sides to scroll through the next and previous change set records in a chronological order.

View timeline of changes to related records

On the time line of changes for a CI record, you can also view a timeline of changes for the CI's related records.

Before you begin

Role required: admin

- Target table: the CI record must be in the Configuration Item [cmdb_ci] table or a descendant of this table.
- Auditing: must be enabled for the table containing the CI.

Procedure

1. Open the timeline for the CI.
2. Select the **Related Records** icon and select related records from the **List of Related Records** to view.
   Click the Related Records icon again to display the related records timeline.

Result

The timeline of changes to the CI's related records is displayed right above the CI's timeline. If you uncheck all related records, the related records timeline is hidden.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

What to do next
Hover over a change bubble on the related records timeline to display details about the change, such as date and number of changed properties. As you change the time interval in focus, or zoom in or out, it affects both the CI timeline and the related records timeline simultaneously.

Export a snapshot of a configuration item

You can export a snapshot of a configuration item from its timeline.

Before you begin
The configuration item must be in the Configuration Item [cmdb_ci] table or a descendant of this table. Auditing must be enabled for the table containing the CI.
Role required: admin.

About this task
You can export a snapshot of the CI to an XML, PDF (Portal), or PDF (Landscape) format.

Procedure
1. Navigate to **All** > **Configuration** > **Base Items** > **All** to open the configuration item list.
2. Open a configuration item record.
3. Open the timeline for the record.
4. Select the bubble representing the time for which you want to export a snapshot of the CI.
5. Click the export icon ( ).
6. Select the file format to use for the export.
   You can download the file to your system for viewing.

Compare CI snapshots

You can compare the properties and relationships of a CI at two different points in its timeline.

Before you begin
The CI must be in the Configuration Item [cmdb_ci] table or a descendant of this table. Auditing must be enabled for the table containing the CI.
Role required: admin.

Procedure
1. Open the timeline for the CI.
2. Click **Compare**.
3. Select a **Start** date and an **End** date.
4. Click **Compare**.

Tracking changes to reference fields

Administrators can track changes to reference field display values.

Since reference fields only store an ID value, the system can normally only audit changes when the ID value changes. By default, the system does not audit changes when a reference field display value changes.

Consider the following situation. A user changes their name from Jane Smith to Jane Miller. Since the user name is the display value for the User table, any previous reference to Jane Smith instead refers to Jane Miller. If the administrator just updates the name of the existing

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

user record, audit and history records will only display the new name Jane Miller. By default, the system does not provide a way to distinguish between changes made under the original user name versus those made with the new user name.

If your auditing policy requires tracking user name changes, you can:

- Create a new user record for the new name and deactivate the previous user record. The system preserves audit records for the old user name and creates future audit records with the new user name.
- Create custom fields and a business rule to save the previous name and the date of the name change. The system can use this information to construct the proper names in audit and history records.

Tracking inserts

By default, the system does not create Audit records for inserts because in a typical instance, inserts can account for over 80% of the size of the Audit table.

Not tracking inserts allows for better performance and a much smaller Audit table. Administrators can enable auditing of inserts by setting the *`glide.sys.audit_inserts`* property to *true*.

Tracking CI Relationships

Changes to a CI relationship (CI Relations, CI/User Relations, or CI/Group Relations) appear in the history of the items on both sides of the changed relationship regardless of whether the change was manual or a result of Discovery.

For example, if the computer alpha has a used by CI Relation with the computer beta, then the history for alpha has a record of when the relationship with beta was established, and likewise, the history for beta has a record of when the relationship with alpha was established. This example illustrates the history displayed when some CI Relations are established, and then one of the relations is removed:

relationship history for any or all CI relationship types, you can turn it off by disabling auditing on the CI relationship tables (CI Relationship [`cmdb_rel_ci`], CI/User Relationship Type [`cmdb_rel_user_type`], or Group Relationship [`cmdb_rel_group`]).

Granular admin roles for Audit tables

Granular admin roles replace broad admin access with targeted, feature-specific permissions. Use these roles to grant the administrative capabilities needed for specific tasks without assigning the admin role.

Granular admin roles for Audit tables

Role name	Feature	Description
audit_viewer	Audit, History and Journal	Provides read access to the sys_audit, sys_journal_field, and sys_history_set tables.
audit_admin	Audit, History and Journal	Provides write and delete access to sys_audit. Manual record modifications should be avoided. For bulk deletions, use system jobs rather than direct deletion.

High Security Settings

High Security Settings refer to several security options available in your instance.

Explore High Security setting	Activate High Security Settings
	
Learn the features and business values of High Security Settings.	Activate the High Security Settings.

Exploring High Security Settings

High Security Settings refer to several security options available in your instance.

The High Security Settings module is activated with the High Security Settings plugin, which is active by default on new instances. If High Security Settings are not active on your instance, see Requesting High Security Settings activation. To learn more about this plugin, see Enable High Security plugin in Instance Security Hardening Settings. Properties for these types of high security settings are available:

- Default property values: To harden security on your platform by centralizing all critical security settings to one location for management and auditing.
- Default deny property: Provides a security manager property to control the default security behavior for table access.
- Security Administrator role: Provides a role to prevent modification of key security settings and resources. The Security Administrator role is not inherited by the admin role and must be explicitly assigned.
- Elevated privileges: Allows users with the security admin role to operate in the context of a normal user and elevate to higher security role when needed.
- Property access controls: Allows security administrators to set the roles required to read and write properties.
- System logs: Are read only.
- Access control rules: Control what data users can access and how they can access it.

Note:

- High Security Settings also automatically activates the Contextual Security plugin, if it is not already active. In addition, Platform Security Settings - High delivers settings and features in the context of increasing the security of your instance.
- The Instance Security Hardening Settings content contains detailed descriptions, and compliance values, for the security-related system properties and plugins in the ServiceNow AI Platform.
- To learn more about each of these properties, see Hardening settings.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

There are two ways to set or change High Security Settings properties.

- Navigate to **System Security** > **High Security Settings**.

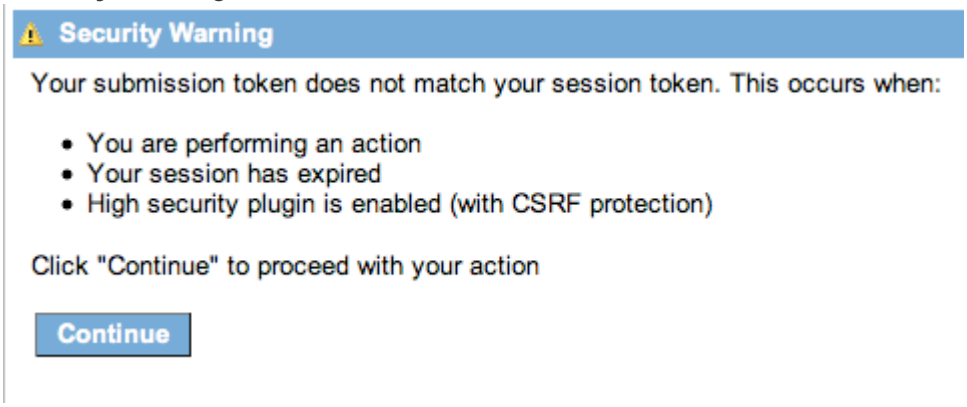
  Options on the High Security Properties page are **Yes** or **No**.

- Navigate to the **sys_properties.list** and search for the property you want to set or change.

  Options in the System Properties table [sys_properties.list] are **true** or **false**.

Property access control

Two additional columns are created in the Properties [sys_properties] table when High Security Settings are active:



- **read_roles**: A comma-separated list of role names that are allowed to read all fields of this property.
- **write_roles**: A comma-separated list of role names that are allowed to write/modify all fields of this property.

Properties listed in the Properties table have **read_roles** of admin, and **write_roles** of security_admin. Users with the admin role can view and read the property values, but must elevate to the security_admin role to modify them.

Notifications

Activation of high security settings also activates security warning messages. The following is an example of a message that appears after an approval.

Security Warning notification

High Security Settings properties

Property	Description	Default Value	Instance Security Hardening Settings
glide.ui.escape_text	Escape XML values at the parser level for the user interface. Prevents reflected and stored cross-site scripting attacks. This property is not	Yes	Escape XML markup

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Description	Default value	Instance Security Hardening Settings
com.glide.security.check_unsanitized_html	Enforces sanitization behavior of translated_html fields on a global level for field assignments.	enforce	None

Activating High Security Settings

The High Security Settings plugin is active by default on all new instances. If it is not active on your instance, you can request the plugin.

Before you begin

Role required: None

Before activating High Security Settings on an existing instance:

1. Review the following information to understand the new behavior:
   - Access Control Lists (ACLs)
   - High Security Settings
   - Default deny property
2. Enable the plugin on a non-production instance. A recent clone of production is preferable.
3. Test the revised functionality, especially the added ACLs and default-deny functionality. Continue testing until the system performs as expected. If users cannot access expected resources, ensure they have appropriate roles and ACL rules to grant them the access.
4. Create update sets of any needed changes so you can apply them to production.

Note: To learn more about this plugin, see Enable High Security plugin in Instance Security Hardening Settings.

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Select **Request plugin** to open the **Activate Plugin** form on Now Support.
3. On the **Activate Plugin** form, provide the following information.

Activate Plugin form

Field	Description
What is your target instance	Select the instance that you want to activate the plugin on.
Which plugin would you like to activate	Select the name of the plugin to activate.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: If the system doesn't list the plugin you want or if you're activating the plugin on an OEM or on-premise instance, select the **Plugin I'm looking for is not listed** check box and then enter the name of the plugin.
Select Maintenance Date and Time	Select the date and time to activate the plugin.

Example

For example, see the following form to activate the Event Management plugin on an instance named SNC Instance.

4. Select **Submit**.
   After the maintenance window, the system installs the plugin on your instance. To confirm the installation, go to the Installed tab in the Application Manager.

Virtual Private Network (VPN)

Use a virtual private network (VPN) to integrate your instance with external data sources over the Internet.

Explore

Learn the features and business values of virtual private network.

Activate

Active the virtual private network.

Configure

Understand how to configure virtual private network.

Exploring Virtual Private Network (VPN)

Use a virtual private network (VPN) to integrate your instance with external data sources over the Internet.

When configuring an integration that uses an encrypted protocol, such as Lightweight Directory Access Protocol (LDAP) or HTTPS, it is good practice to use the Internet as a transport mechanism.

However, there may be security or network architecture requirements that dictate the use of a site-to-site Internet Protocol Security (IPSEC) Virtual Private Network (VPN) connection between the datacenters and your business networks. The VPN supports the necessary encrypted communication between the instance and your network.

⚠ Warning:

When a VPN tunnel is initiated, it operates as site-to-site connection. This means that the endpoint on your infrastructure receives an IP address, referred to as an encryption domain. This public IP can be accessed by any instance within the same data center.

For example, if you have an internal web service and establishes a VPN tunnel, your instance is able to reach the internal endpoint as well as all your other instances in the same data center.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

VPN connections

The ServiceNow VPN infrastructure uses pairs of Cisco adaptive security appliance (ASA) devices that serve as VPN termination points.

The VPN between the instance and your network utilizes your existing networking hardware to support communications. It is not necessary to install a piece of hardware. Because each customer has a unique configuration, the instance has a flexible VPN solution. the instance has built tunnels to Checkpoint, Juniper, Nortel, and other IPSEC VPN-capable devices.

The VPN connections between the instance and your network are created to support the encrypted flow of traffic into your network. Frequently, integrations that use the VPN do not have encryption as part of the underlying protocol. For example, LDAP over the VPN versus LDAPS over the Internet and HTTP over the VPN versus HTTPS over the Internet.

The network does not allow any inbound-to-ServiceNow integration or end-user-to-ServiceNow traffic to traverse a VPN connection. This restricted communication includes end-user access to the platform, administration of the platform, web services integrations, and other integrations that are configured to use a MID Server. All such inbound communication to the instance must be performed over the Internet using HTTPS. This configuration provides an encrypted communication channel. The encryption channel, along with IP access control, meets the security requirements for this traffic flow.

This restriction applies to inbound traffic only. Responses to outbound requests that the instance initiates do traverse the VPN tunnel.

Addresses for VPN communication

To prevent conflict or overlap with internal ServiceNow networks or with another internal IP address schemes in your network, all tunneled traffic in the encryption domain must use non-RFC-1918 addresses on both sides of the tunnel.

ServiceNow provides a single IP address for the source of queries into your network. You must provide Network Address Translation (NAT), non-RFC-1918 addresses for each host that is integrating with your instance. These public addresses need to be owned by your organization. Third-party addresses cannot be used inside tunnels. Additionally, the encryption domain must not contain the IP address of the VPN peer.

Redundant tunnels

There are two ways to build redundancy for your tunnels:

- Using the same encryption domain behind both of your peers. This is the preferred method.
- Using a different encryption domain behind each peer.

With the first method, you need to provide the same NAT address behind each of your peers to create a connection path using that address to your server. The path to your server could be the same physical machine or a mirror which provides identical services. With this method, your instance would use the same IP address to connect to your servers regardless of whether your primary or secondary tunnel is active. If you have more than one server, follow this same scheme for your additional servers. This method provides the most transparency to your users and is recommended.

The second method requires configuration in your instance to provide the redundancy. When the tunnel is used for LDAP, for example, you could provide redundant LDAP servers in your instance. Note that this method requires the connection to the first configured LDAP server to timeout before the instance attempts to connect to the secondary server. Because of this additional time delay, this solution should only be implemented if the first option is unattainable. Also note that

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

not all services can be configured for redundantly in your instance. If you are using a VPN tunnel for something other than LDAP and redundancy is required, check that your configuration can support multiple addresses, or see the first option above.

Alternatives to using a VPN

These alternatives provide a simpler way to connect your instance to the resources in the ServiceNow data centers and provide better encryption. Additionally, you can avoid any issues that VPN downtime might cause, such as making your instance unavailable to users if there is an issue with the VPN tunnel.

Single sign-on and MID server

Consider using a combination of Single Sign-On (SSO) for authentication and the MID Server for user data synchronization, rather than using a VPN to connect your LDAP server to your instance. For integrations other than LDAP, consider using certificate-based encryption.

You can use the LDAP listener on a MID server to synchronize your user table in near real time.

The advantage of this approach is that there are no firewall holes, routes, VPN tunnels, or other special network settings to configure and maintain. The SSO/MID-Server solution is the most flexible, secure, and cost-effective method to achieve the complete LDAP integration.

LDAP over SSL

Another alternative to using a VPN tunnel is to configure LDAP Over SSL (LDAPS) directly over the Internet. You can configure a read-only domain controller and lock the instance down in your DMZ using only the instance's source addresses and the destination ports of your choice. Since the ports for LDAP are configurable in your instance, you can perform a port address translation (PAT) if desired. With LDAPS, you control the certificate that is uploaded over an encrypted channel to the instance, (see Uploading a certificate to an instance). The packets cannot be encrypted or decrypted without the certificate.

The advantage of this approach is that it provides a stronger encryption and decryption mechanism. A VPN can only encrypt and decrypt the traffic between the two peers sitting on the Internet with a coordinated pre-shared key, similar to a password. LDAPS provides a longer encrypted path, end-to-end, at the application layer and with a certificate that is far more complicated than a pre-shared key that the IPSec tunnel uses.

VPN setup

From the time that a VPN request is submitted, it typically takes one week or less to complete the VPN build. To support the redundancy requirements of your instance and your organization, a minimum of two and a maximum of four VPNs are provisioned (from the active site to your active site or the active site to your DR site, and so on).

It is good practice for the encryption domain to be as specific as possible. Ideally, the encryption domain would include only the specific hosts that are required for the integrations. A large encryption domain can create opportunities for routing discrepancies (VPN versus Internet).

To create the VPN, the instance does the following:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

1. Provides the VPN peer and host addresses from each data center.
2. Builds the necessary VPN connectivity from two data centers into your network. To support redundancy and disaster recovery (DR) requirements, the VPNs can be provisioned from two data centers into two networks.

The instance does not support building multiple VPN tunnels into a customer network for the purpose of connecting to multiple geographic regions or subsidiaries. You should perform any inter-site routing, traffic distribution, or traffic shaping within your own internal network, rather than having multiple VPN tunnels.

Activating a VPN service

For all VPN requests, including provisioning, modifications, or general questions, use the Service Catalog VPN Request form.

Before you begin

Role required: admin

Procedure

1. Navigate to .
2. Select the **Automation Store** tab.
3. Use tree on the left to navigate to **All automations** > **Service catalog** > **Cloud Infrastructure**.
4. Select **VPN Requests**
5. Select the appropriate VPN request type.
6. Answer the questions.
   Questions vary depending on the request type selected.
7. Click **Submit**.

Result

Once your request is submitted, ServiceNow will work with your network engineer(s) to test and validate that the VPN is successfully passing traffic. To ensure that your questions are answered in a timely manner, please address VPN-related questions during this process.

Configuring an address for VPN communication

To prevent conflict or overlap with internal ServiceNow networks or with another customer's internal IP address schemes, the instance requires that all tunneled traffic in the encryption domain use non-RFC-1918 addresses on both sides of the tunnel.

Before you begin

Role required: admin

About this task

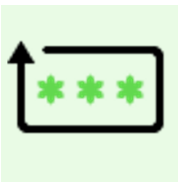
The instance provides a single IP address for the source of queries into your network.

Procedure

Provide Network Address Translation (NAT), non-RFC-1918 addresses for each host that is integrating with the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Platform Privacy

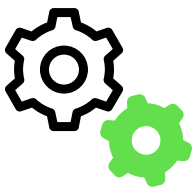


Privacy enables you to mask the sensitive date on the instance.

Data Privacy

Use Data Privacy to classify sensitive data and to remove personally identifiable information (PII) from user data in a production instance and anonymize data in non-production instances.

Data Discovery



Use Data Discovery to identify sensitive data within an instance to classify, protect, or report.

Data Anonymization

Data anonymization provides a way to easily transform data so that it is unidentifiable and more compliant with data privacy regulations.

Data Classification

Group data by type, using pre-defined or user-defined data classifications. If you have an assigned data classification administrator or auditor role, you can administer different data classes or visually analyze the current state of different types of data within the instance.

Exploring Data Privacy

Use Data Privacy to classify sensitive data and to remove personally identifiable information (PII) from user data in a production instance and anonymize data in non-production instances. Once anonymized, the user data is no longer considered regulated private information.

Developers must work with data on non-production instances to ensure that their implementations are working as expected. While importing data from your production instance is a useful way to simulate production, it presents a security risk. Administrators can use data privacy to provide developers with data that does not contain private information to work safely in a non-production environment.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data classification

Identify and classify your sensitive data according to pre-defined criteria determined by the level of sensitivity of the data types in your instance. Data sensitivity levels help determine how each type of classified data should be handled. There are several pre-defined classes provided with base level data privacy. Use the classification section of Data Privacy to label and group data within your instance. Add classes, view data class structure and classify data. Group data by type, using pre-defined or user-defined data classifications.

User data anonymization

As an administrator, you define whether to anonymize all information for all users or for a subset of users. When anonymized, data for the selected user records is replaced with randomized values or values you define. When replacing values, the data structure can be preserved using various techniques.

Data privacy options

- Data privacy (Classic): First use the data classification app to group your data by type, using pre-defined or user-defined data classifications. Then create data privacy techniques and jobs to anonymize PII.
- Data privacy (Store App): Classify and anonymize your data all from within the data privacy app.

Installation details

You must have the following applications installed on your instance:

- Data Privacy (Classic) [com.glide.data_privacy]
- Data Privacy [sn_dp_store_app]
- Data Discovery [sn_data_discovery]
- Data Discovery APIs[com.glide.data_discovery]

Here is the how the installation works:

- Installing the Data Privacy Store App will auto install the Data Discovery Store App, Data Privacy (Classic) plug-in, and the Data Classification plugin.
- Installing the Data Discovery Store App will auto install the Data Discovery APIs plugin

Considerations

- Only classified data can be anonymized. For information on data classes and classification, see Data classification (Classic) or Data classification Store App.
- PII in logs and other auditing data are not anonymized.
- Only structured data can be anonymized. Unstructured data, such as Journal fields, comments, attachments, and other fields where partial text may represent PII is not anonymized. See Supported field types for anonymization for more information.
- Integrations with single sign-on (SSO) systems may resynchronize user information from their source of truth systems. There is no mechanism in place to ensure the permanency of the de-identification of sys_user data. For information on user administration and sys_users see User Administration.

Learn more about Data Privacy for ServiceNow Otto

Configure

Configure Data Privacy for ServiceNow Otto

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

Data Privacy for ServiceNow Otto detects and masks sensitive data based on Regex and Named Entity Recognition (NER) data patterns. Enabling NER data patterns requires customers to have a Vault license as well as an additional $0 SKU associated with the Vault license. Also, customers must have the latest version of the GenAI Controller (`sn.generative.ai`) installed on their instance (which requires the admin role).

There are associated rate limits on how much data can be processed when using Named Entity Recognition (NER) data patterns for ServiceNow Otto. Once these limits are exceeded, any applicable Regex based data masking that was configured will apply for all ServiceNow Otto prompts, skills, and agentic executions.

Important:

- Not all model providers are available for customers with in-country SKUs, and some AI products/features are currently unavailable for in-country customers. For more information, see the KB1584492 article in the Now Support Knowledge Base. Be sure to check for model provider availability updates in future releases.
- Some AI products/features are currently unavailable for customers in the FedRAMP, NSC DOD IL5, or Australia IRAP-Protected data centers, self-hosted customers, or in other restricted environments. For more information, see the KB0743854 article in the Now Support Knowledge Base. Be sure to check for availability updates in future releases.
- Some AI products/features are currently available only for customers in some regions. Be sure to check for availability updates in future releases.
- Some AI products and skills are not available in Regulated Markets. For more information, see KB2593939: Regulated Markets AI Products/Skills Not Available. Be sure to check for availability updates in future releases.

Exploring Data Privacy for ServiceNow Otto

Learn more how Data Privacy for ServiceNow Otto enhances your ability to protect sensitive data.

Data Privacy for ServiceNow Otto overview

Personally identifiable information (PII) can be masked so that it does not get processed from generative AI prompts. Placeholder text and anonymized data are sent with the prompt instead. These values are replaced with the original text after the large language learning module (LLM) response has been received. This two-way masking ensures that end users receive accurate responses, but sensitive data is not exposed to the LLM.

There are some considerations for configuring Data Privacy for ServiceNow Otto. See Configuring Data Privacy for ServiceNow Otto for configuration details.

Important:

Data Privacy for ServiceNow Otto detects and masks sensitive data based on Regex patterns and does not support contextual(model-type) data patterns

Configuring Data Privacy for ServiceNow Otto

Configure a data privacy advanced configuration to de-identify personally identifiable information (PII) in generative AI applications.

Before you begin

You must have the following applications installed on your instance:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Data Privacy (Classic) [com.glide.data_privacy]
- Data Privacy [sn_dp_store_app]
- Data Discovery [sn_data_discovery]
- Data Discovery APIs[com.glide.data_discovery]

Installing the latest version of the Generative AI controller will auto install the Data Privacy Store App(sn_dp_store_app). The Data Privacy Store App will auto install the Data Discovery store app[sn_data_discovery], Data Privacy (Classic)(com.glide.data_privacy) plug-in, and the Data Discovery APIs[com.glide.data_discovery].

Role required: now_assist_data_privacy_admin

Important: You do not need a full active license to configure Data Privacy for ServiceNow Otto.

Procedure

1. Navigate to **All** > **Data Privacy (Classic)** > **Privacy Policy Advanced Configuration**.
   If you previously used the Sensitive Data Handler to help de-identify data for generative AI, you may already see a privacy policy configured. Your previously configured regular expressions have been migrated as part of your upgrade. If you already have a data policy for ServiceNow Otto, skip to step 6.
2. Select **New**.
3. Enter a name for the privacy policy.
4. In the **Data Channel** field, select the data channel to be used.

Channel	Description
Data Kit	Data, which AI models are using for evalua tion, is sanitized by discovering and de-identi fying sensitive data
Data Extraction	Data is sanitized before being sent for model training
Now Assist	Data is sanitized before being sent to GenAI Controller

5. Set **Active** to `true`, then select **Submit** to create the policy advanced configuration.
   Only one policy configuration for each data channel can be active at a time. To activate a new policy advanced configuration, you must set **Active** to `false` for all other policy configurations on that data channel.
6. After you're redirected to the list of policy advanced configurations, open the record you created.
   Open the existing record with the ServiceNow Otto data channel if one is already present.
7. To add a data pattern to de-identify, select **Select Data Patterns**.
8. **Optional:** To create your own data pattern, see Configure Data Discovery patterns.
9. Select your data patterns, then select **Save**.

Result

Data caught by the regular expressions selected in the data patterns is de-identified for generative AI applications. In this example policy, it is configured to catch a series of active data patterns and then use the data extraction data channel.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data privacy for inbound emails

The inbound email channel enables organizations to discover and mask sensitive data in inbound emails through the Data Privacy framework. This replaces the previous approach which used Active Data Patterns with a centralized, streamlined policy-based experience for managing sensitive data in emails.

The inbound email channel within the Data Privacy module that allows administrators to define and manage policies to detect and redact sensitive data in inbound emails and any associated inbound actions. This requires customers to have the Sensitive Data Redaction for inbound emails plug-in installed on their instance.

Migration of existing configurations

For customers upgrading to Brazil with existing email redaction configurations:

- **Automatic migration:** Upon upgrade, existing email redaction configurations are automatically converted into email channel policies.
- **Pattern preservation:** Active data patterns used in the old plug-in are migrated to the new email channel policy.
- **Default policy:** If no active patterns exist, a default email policy is created with no patterns, allowing administrators to configure as needed.

Migration is transparent to end users as defined in the policy; masking continues seamlessly after the upgrade.

Limitations and considerations

- **Pattern accuracy:** Sensitive data patterns may have false positives or false negatives depending on pattern specificity.
- **Email attachments:** Masking may not apply to sensitive data within email attachments; verify scope with your team.

Create an inbound email channel policy

Create a new policy for the inbound email channel to define sensitive data patterns that should be masked in inbound emails.

Before you begin

Role required: data_privacy_admin and admin

Procedure

1. Navigate to **System Security** > **Data Privacy** > **Anonymization**.
2. Select **Create new policy**.
3. Select **Real time data** as the data policy type.
4. Enter a descriptive name for the email channel policy.
   Use a clear name such as "email Credit Card Masking" or "Inbound Email PII Redaction" to indicate the policy's purpose.
5. Choose **Inbound email** as the **Data to process**.
6. Select **Continue**.
7. Select **Select data patterns** to choose the sensitive data patterns to be masked in inbound emails.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. From the available patterns list, select one or more patterns (for example, Credit Card, Social Security Number, Email Address).

b. Select **Save** to save the data pattern choices.
Patterns define what constitutes sensitive data in the email content. Multiple patterns can be selected if emails may contain different sensitive data types.

8. Select **Save** to save the policy in draft status, or **Publish** to make it active.
Once activated, the policy begins monitoring inbound emails and masking sensitive data according to the configuration.

Data Privacy for Virtual Agent

You can use Data Privacy to detect and mask the sensitive data and PII during a Virtual Agent conversation.

Before you begin

Role required: virtual_agent_data_privacy_admin

About this task

Use Data Privacy to detect and mask the sensitive data and PII during a Virtual Agent conversation. Data Privacy is replacing the depreciated Sensitive Data Handler, see Deprecation Process [KB0867184] for more information. The setup process may vary depending on if Sensitive Data Handler was previously installed and configured.

Note: If you have previously configured Sensitive Data Handler your settings will be migrated to Data Privacy as a policy. See Create anonymization policies for more information.

Procedure

1. Navigate to **All** > **Conversational Interfaces** > **Settings**.
2. Under **Sensitive data detection**, select **View all**.
If the button reads **Get data privacy**, you will need to install the Data Privacy plugin to continue. See Activate data privacy (Classic) for more information
3. Set the slider to **Active**.
4. **Optional:** If Data Privacy is not yet installed you will be prompted to install the Data Privacy plugin to continue, see Activate data privacy (Classic) for more information.
5. Select the appropriate conversation flow:
   a. Requester to agent - detect and mask sensitive data entered by the requester in an Agent Chat conversation.
   b. Agent to requester - detect and mask sensitive data entered by the agent in an Agent Chat conversation.
   c. Requester to Virtual Agent - detect and mask sensitive data entered by the requester during a Virtual Agent conversation.

   Note: You must select at least one conversation flow.

6. Select **Manage in Data Privacy**.
If you have configured Sensitive Data Handler before, your settings will be migrated as a policy to Data Privacy
7. Create a new Data Privacy policy for Virtual Agent, see Create anonymization policies for more information on Data Privacy policies.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data privacy (Classic)

Data privacy (Classic) is available as a family release. The last family updates were released in the Tokyo launch.

Activate data privacy (Classic)

You can activate the data privacy plugin (com.glide.data_privacy) for Platform Security if you have the admin role. The application includes demo data and installs related ServiceNow® Store applications and plugins if they aren't already installed.

Before you begin

Data privacy requires a separate subscription from the rest of the ServiceNow AI Platform®.

To purchase a subscription, contact your ServiceNow account manager. When you purchase a subscription, certain plugins are activated automatically. If a paid plugin isn't activated automatically, you can manually activate it from the All Applications list in your instance.

Note: Before purchasing a subscription, you can evaluate Data Privacy(Classic) and Data Discovery with a 30 day trial period. After your trial expires you will no longer be able to discover data or run anonymization jobs in without a license.

Role required: admin

About this task

The following items are installed with data privacy:

- Plugins
- Roles
- Tables

For more information, see Installed with data privacy (Classic).

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the Data Privacy plugin (com.glide.data_privacy) using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note: When domain separation and delegated admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Installed with data privacy (Classic)

Learn about the components installed with the data privacy plugin (com.glide.data_privacy).

Data privacy (Classic) configuration

Learn how to create data privacy techniques and policies, and how to create and execute data privacy jobs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data privacy techniques

Data privacy techniques are options you select to determine how your data is anonymized. You must create a data privacy technique to reference in the data privacy job. See Create a data privacy technique configuration to associate a privacy technique to an associated **Privacy technique configuration**.

Data privacy policies

Configure a data privacy policy to specify which data privacy techniques are used when anonymizing your data. See Create a data privacy policy for details.

Data privacy jobs

Data privacy jobs use all of these components to anonymize your data. For more information on these jobs, see Configure a data privacy job.

Create a data privacy technique configuration

Create a data privacy technique configuration to customize how data privacy anonymizes your data.

Before you begin

Role required: data_privacy_admin and admin

Procedure

1. Elevate to the **data_privacy_admin** role.
   For details on role elevation, see Elevate to a privileged role.
2. Navigate to **System Security** > **Data Privacy** > **Privacy Technique Configuration**.
3. Click **New**.
4. In the **Name** field, enter a name for your privacy technique configuration.
5. In the **Privacy Technique** field, select a privacy technique.

Data privacy techniques

Technique	Description
No Action	This technique is a placeholder. It does not modify fields when selected.
Random Replace	This technique swaps values with randomly generated values. String and Number data can use this technique.
Selective Replace	This technique does a selective replace of String data. All characters between the input's start and end indices are replaced with the character you choose. You can specify characters to exclude from masking: ○ start_index: Technique masks data starting at the specified character. If left blank, masking begins with the first character. ○ end_index: Technique masks data from the start of the string to the specified character.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Technique	Description
	If left blank, masking ends with the last character. ○ exclude_char: Define a character to exclude from masking. ○ replacement_char: Define a character used for masking. If none is provided, asterisks(*) are used by default.
Static Replace	This technique swaps values with static values. String, Number, and Date data can use this technique: ○ date_time_value: Replace Date values with this date. Use the yyyy-MM-dd HH:mm:ss format. ○ date_value: Replace Date values with this date. Use the yyyy-MM-dd format. ○ number_value: Replace Number values with this number. ○ string_value: Replace String values with this text.
Remove	This technique removes values, replacing them with empty (null) values.

Note: Previously supported value **Replace** is deprecated and renamed **Replace-Deprecated** and should not be used.

6. Right-click the header and click **Save** in the context menu.
   After the record is saved, the **Privacy Parameterized Values** list appears.
7. Use the records in the **Privacy Parameterized Values** list to customize your data privacy technique configuration.
   The available parameterized values depend on which privacy technique you have selected. There are no parameterized values for the **No Action** and **Remove** techniques.

Privacy parameterized values for Selective Replace

Privacy Technique Parameter value	Description	Default value
char_to_replace	Character to use when replacing values using a selective replace.	*
end_index	Technique masks data from the start of the string to the specified character. If left empty, masking ends with the last character.	(Empty)
exclude_char	Character to skip masking. Only a single character can be used in this value. If more	(Empty)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Privacy Technique Parameter value	Description	Default value
	than one is entered, the first character is used.	
start_index	Technique masks data starting at the specified character.	1

Privacy parameterized values for Replace

Privacy Technique Parameter value	Description	Default value
date_time_value	Replace date and time values with this date. Use the yyyy-MM-dd HH:mm:ss format.	1988-11-11 10:10:10
date_value	Replace date values with this date. Use the yyyy-MM-dd format.	1988-11-11
number_value	Replace Number values with this number.	1234567
preserve_data_length	Set to **true** to preserve data length. De-identified data will have the same length as the original data.	true
string_value	Replace String values with this text.	TEXT123
use_random_generated_value	Set to **true** to replace data with randomly generated values. Only String and Number data can be replaced with random values. This option overrides static values.	false

8. Click **Save**.

Create a data privacy policy

Configure a data privacy policy to specify which data privacy techniques are used when anonymizing your data.

Before you begin

The data privacy configuration defines tables, sys_user and other, and columns to the de-identified, depending on the use case and specifies parameterized types of the techniques to be used while de-identifying data.

Note: To complete a privacy configuration, you must first configure a data privacy technique configuration. See Create a data privacy technique configuration for more information.

Role required: data_privacy_admin and admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Elevate to the **data_privacy_admin** role.
   For details on role elevation, see Elevate to a privileged role.
2. Navigate to **System Security** > **Data Privacy (Classic)** > **Privacy Policy Configuration**.
3. Select **New**.
4. In the **Name** field, enter a name for your privacy policy configuration.
5. In the **Data Class** field, select the data class to use with this policy.
   Data privacy policies can only apply to classified data, for more information on data classification, see Data classification.
   After selecting a data class, the **Privacy Classified Field Techniques** and **Privacy Primary Reference Links** lists display on the form.
6. **Optional:** Select **Apply to All Data in Class** to apply anonymization to all data in the chosen data class.
   If you don't select this field, your data privacy processor users can choose which users to anonymize when creating data privacy jobs. If you select this field, that option is not available.
   - **Apply when Cloning**: This option becomes available. When selected, the privacy configuration executes during data privacy clone.
   - **Application Order**: A data privacy job for Postclone configuration with a higher Application Order might start before another job with lower order.

   > **Important:** Avoid creating multiple data privacy policies with the same Application Order, as the resultant processing order for those with the same order will be inconsistent.

7. **Optional:** Select **Supports Rollback** to enable the ability to de-anonymize the data from a data privacy job.
   See Roll back a data privacy job for more information.
   After selecting **Supports Rollback** when creating a data privacy job, the option to roll back the job becomes available.
8. Select the **Privacy Classified Field Techniques** tab to display the **Privacy Classified Field Techniques** list.
9. Select an entry in the **Table** field to open the **Privacy Technique Configuration** field for each list entry.
   The **Privacy Classified Field Techniques** list displays all the data to be anonymized in your selected data class. For each of these entries, you must select a privacy technique to apply.
10. Select a **Privacy Technique Configuration** to apply.

    > **Important:** If you aren't anonymizing an entry, select the **DoNothing** technique rather than leaving the entry empty. Policies with empty values in the **Privacy Technique Configuration** field can't execute when used in data privacy jobs.

11. Select **Submit** or **Save** to save the record.

What to do next

Configure a data privacy job.

Configure a data privacy job

Configure a data privacy job on your production instance to use anonymized data on your non-production instance for user and data class jobs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

The data privacy job supports two de-identification use cases:

- Sensitive data of specific sys_users
- Sensitive data of particular data class.

Role required: data_privacy_processor and admin

Procedure

1. Elevate to the **data_privacy_processor** role.
   For details on role elevation, see Elevate to a privileged role.
2. Navigate to **System Security** > **Data Privacy** > **Data Privacy Job**.
3. In the Data Privacy Jobs list, click **New**.
4. In the form, fill in the fields.

Data privacy job fields

Field	Description
Name	Name of the job.
Description	Description of the job.
Privacy Configuration	The privacy policy configuration to use for this job. For detail on Privacy policy configurations, see Create a data privacy policy.
Frequency	○ **Run Once**: The job will run once in the specified time window. ○ **Weekly**: The job will run each day of the **Day of the week** field in the specified time window. ○ **Monthly**: The job will run each day of month as entered in the **Day of the month** field in the specified time window.
Users	Select the users or group of users to be anonymized in this job. Up to 1000 users of a group can be processed. **Note:** This field displays only when the selected privacy policy condition requires a selection of user records.
Dry Run	Run the job as a test. No records are affected when running this job. Results are displayed in the **Summary** field as though the job had executed. **Note:** **Dry Run** must be turned off when configuring a data privacy job with rollback. See Roll back a data privacy job for details.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	The Dry Run capability has the following considerations and limitations to be aware of: ○ Dry run preview does not work for anonymization of encrypted columns. ○ There is an upper limit of 200k records per table. ○ Sample dry run - 10 preview records per column are allowed. ○ Detailed dry run - 10 preview records per data pattern per column are allowed; for data pattern anonymization, the limitation is `10 *` the number of active data patterns.
State	State of the data privacy job: ○ **Completed**: Job completed successfully. ○ **Ready to Schedule**: Default state for new jobs. ○ **Rollback in progress**: The job has been set to roll back anonymization. ○ **Rollback complete**: The anonymization job rollback has successfully completed. ○ **Completed with Errors**: The job completed but has errors. See Data Privacy Job Logs for more information. ○ **Error**: Job did not complete and had an error. See Data Privacy Job Logs for more information A read-only field.
Estimated record count	The estimated number of records this job affects. A read-only field.
Summary	A read-only field that displays the results of the job when you execute it.
Time window start	The start of the time window to run this job. The job will run after the time entered in this field. A valid time value is in Coordinated Universal Time based on a 24 hour time notation.
Time window end	The end of the time window to run this job. The job runs before the time entered in this field. If the job has not yet completed, the job will pause and resume at the next time window start. The end time must be after the start time. A valid time value is in Coordinated Universal Time based on a 24 hour time notation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Right-click the form header and select **Save** from the context menu.
   After saving the record, the **Schedule Job** and **Delete Job** buttons appear.
6. Click **Schedule Job** to run your job.
   The job runs between the times selected in the **Time window start** and **Time window end** fields. If the job has not completed during the start and end time window, the job will continue at the next time window start.

   Note: A job can only be executed once, even if **Dry Run** is selected. To run the same job again, create a data privacy job using the same field values.

7. **Optional:** Choose one of the following functions:
   - **Cancel Job**: Cancels the data privacy job.
   - **Pause**: Pauses job and rollback recording, if rollback has been selected. A warning message will display after a three-day expiry period for rollback contexts. See Roll back a data privacy job for details.
   - **Resume**: Restarts a paused job. Rollback is not supported for resumed jobs if paused. Cancel the job and create a data privacy job. The recording uses an unexpired rollback context.

Data privacy job rollback

Database changes are captured for actions like jobs and scripts so that the changes can be rolled back. Roll back a data privacy job for when human error inadvertently anonymizes incorrect user information. The rollback de-anonymizes the data from the data privacy job.

Overview

- Rollback is limited to a few days, per the configured expiry duration of the RollbackContext of the new RollbackType *REDACT*. After expiration of the RollbackContext associated with a data privacy job, the rollback function is no longer available for that job.
  - A rollback context from de-anonymization is saved for three days by default.
  - The default expiry time can be set to a value greater than one by the data privacy administrator in the **RollbackContext** of the new **RollbackType** *REDACT*. Set the value in the Glide system property *glide.rollback.expiration_days_redact*. See Roll back and delete recovery.

    To learn more about adding or creating a system property, see Add a system property.

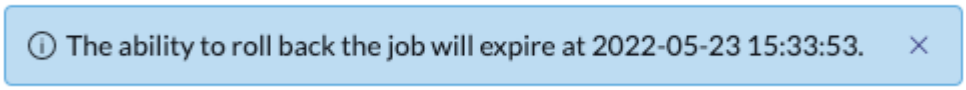
    for additional information.
- Rollback is available for data privacy jobs that are in a Completed, Canceled, or Error state.
- For every successful sys_user de-anonymization job which is configured with a data privacy policy with rollback support turned on, a rollback context is created. There can be at most one rollback context per data privacy job.

Roll back a data privacy job

Roll back a data privacy job on your non-production instance that uses anonymized data from your production instance to a state prior to de-identification of a data class or user job.

Before you begin

Role required: data_privacy_admin or data_privacy_processor, and admin



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Elevate to the **data_privacy_processor** or **data_privacy_admin** role.
   For details on role elevation, see Elevate to a privileged role.
2. Navigate to **All** > **System Security** > **Data Privacy** > **Data Privacy Job**.

   Note: In advance, a data privacy policy configuration that supports rollback must be created. Create a data privacy policy.

3. Create a data privacy job and select a Privacy Configuration that supports Rollback.
   See Configure a data privacy job.
4. Schedule the job for data anonymization.
   - After the job has run, the data will be anonymized for the selected configuration.
   - A message displays in the job informing of the expiration time.
     Within the expiry period you have the ability to roll back the job.

5. Elevate to the **data_privacy_processor** role.
6. Open the data privacy job to be rolled back.
7. Select **Rollback** to de-anonymize the data.

Data privacy clone

As customer data are cloned from a source to a target instance, typically from production to non-production, sensitive data are de-identified on the target instance.

A data privacy administrator configures post-clone policies. After the post-clone script completes on the target instance, the users will see de-identified data and will not have access to the original data. Data privacy administrators can configure de-identification policies to apply on the target instance when cloning to ensure that the target instance will not have original sensitive data. An order is specified for the policy relative to other policies to be executed.

Note: Data privacy cloning is not available on self-hosted instances.

Data privacy clone has the following additional attributes:

- The data privacy plugin creates the post clone script to be executed on the target instance.
- Data privacy jobs created for PostClone configuration can run in parallel if they don't involve the same tables.
- A data privacy job for Postclone configuration with a higher Application Order might start before another job of lower order, if the job with the higher order does not involve any table related to other lower order job.
- With the data privacy plugin, data privacy tables are by default in the Clone Data Preservers table set.
- An attempt to add a data privacy table (dp_[table]) to Clone Exclude Tables will get a warning, that table should not be excluded.

Configure data privacy clone request

Data privacy clone integration is configured using a PostClone script to create and execute data privacy jobs for configured policies on the target. After running the script, users will see de-identified data and will not have access to the original data.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin
Role required: data_privacy_clone_processor, data_privacy_admin, and admin

Procedure

1. Activate the data privacy plugin (sn_dp_store_app) on the source instance.
   The plugin can only be installed by Customer Service and Support.
   The data privacy PostClone script is installed.
2. Elevate to the **data_privacy_admin** role.
   For details on role elevation, see Elevate to a privileged role.
3. Navigate to **System Security** > **Data Privacy** > **Privacy Policy Configuration**.
4. Create a Privacy Policy configuration.
   Select **Apply to All in Data Class** and **Apply when Cloning**. See Create a data privacy policy for more information.
5. Back up data privacy configurations.
6. As the data privacy admin, submit a clone request.

Result
The data privacy PostClone script executes on the target Instance and The PostClone script creates a data privacy federated job record on the target instance. The federated job creates and executes a data privacy job for each post-clone policy, in Application Order, on the target instance.The backup source is cloned to the target Instance. Data privacy PostClone script creates and executes data privacy jobs for configured policies on the target instance.

The elevated data privacy clone processor can log on to the target instance and monitor the post-clone federated job state on the dp_federated_job.list and dp_job.list.

Data Privacy Job Logs

Review errors from Data Privacy jobs.

Before you begin
Role required: data_privacy_admin, data_privacy_clone_processor, data_privacy_processor, data_privacy_auditor

About this task
Use the **Data Privacy Job Logs** to review failed discovery, classification, and anonymization jobs.

Procedure

1. Navigate to **System Security** > **Data Privacy(Classic)** > **Data Privacy Job Logs**.
2. Review the table

Data Privacy Job Logs table

Label	Description
Created	Who or what created the log entry
Level	The severity of the error
Message	Description of the cause of the error
Source	Plugin source of the error
Type	The type of error that occurred

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Label	Description
Code	Error code that occurred
Job Table Name	The table the job is located in
Job Id	The job ID
Target Table Name	Table the job executed on
Target Table Column	Column the job executed on
Target Table Record	Record the job executed on

Data privacy

The data privacy store app is a Next Experience refresh for data classification and data privacy with modern look, feel, and usability. Data privacy store app is supported in Utah and above.

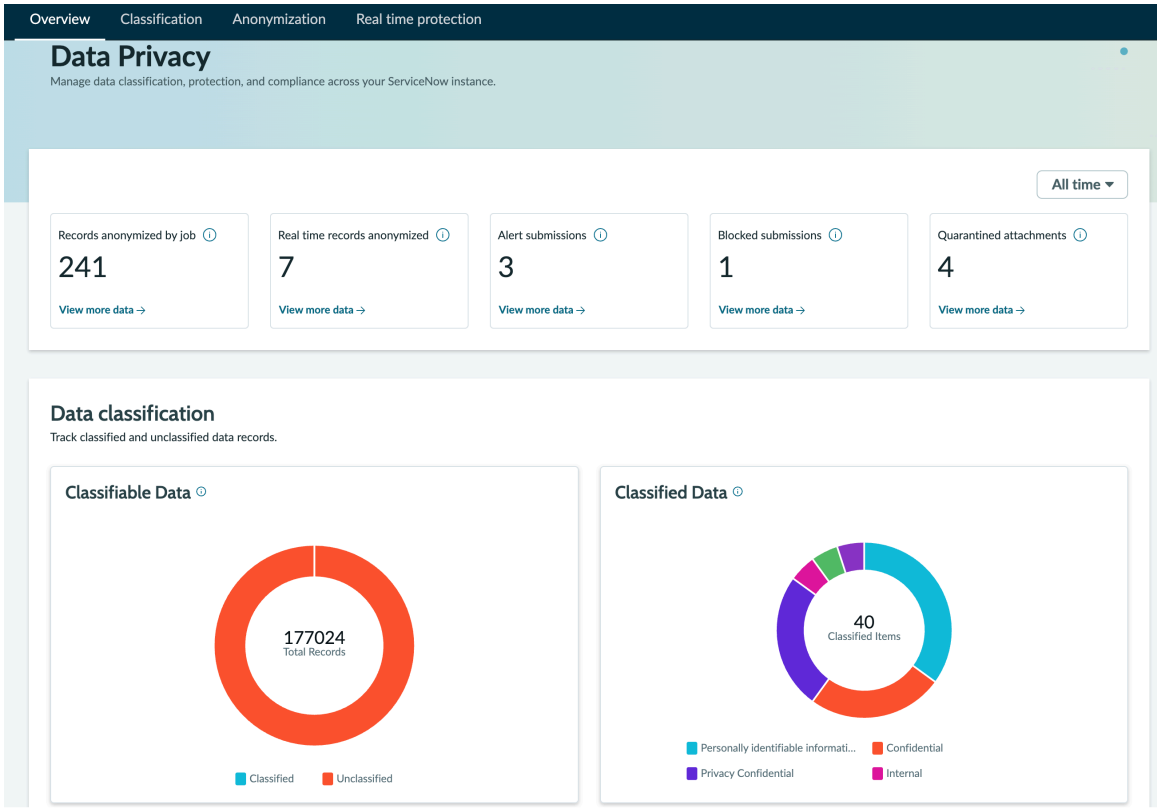
Data privacy is comprised of several components, Overview, Classification, and Anonymization.

Overview

Use the Overview section as a starting point to manage your data and data privacy compliance. See Data privacy overview for details.

Classification

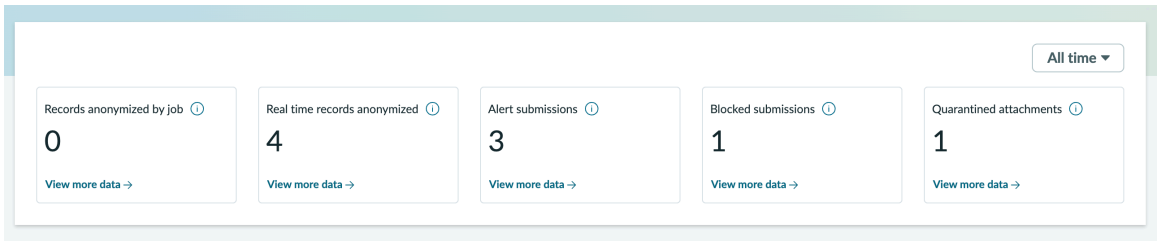
Data classification is the process of organizing data into categories that make it easy to retrieve, sort, and store for future use. Using a classification system helps to focus on confidentiality and security policy requirements. Classify data to be used for anonymization. For information on data classes and classification, see Data classification.



Data privacy overview

The Overview homepage is a starting point to manage your data and data privacy compliance.

The Overview dashboard reports the current state of data classifications and anonymization jobs within your instance. You can view your data with the Overview dashboard to see how much data can be classified, the data classes available, the amount of data in each class, and more.



Note: Some classified data is broken into different categories. Selecting a sub-category in any chart will add or remove the category from the overall chart and adjust the counts.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

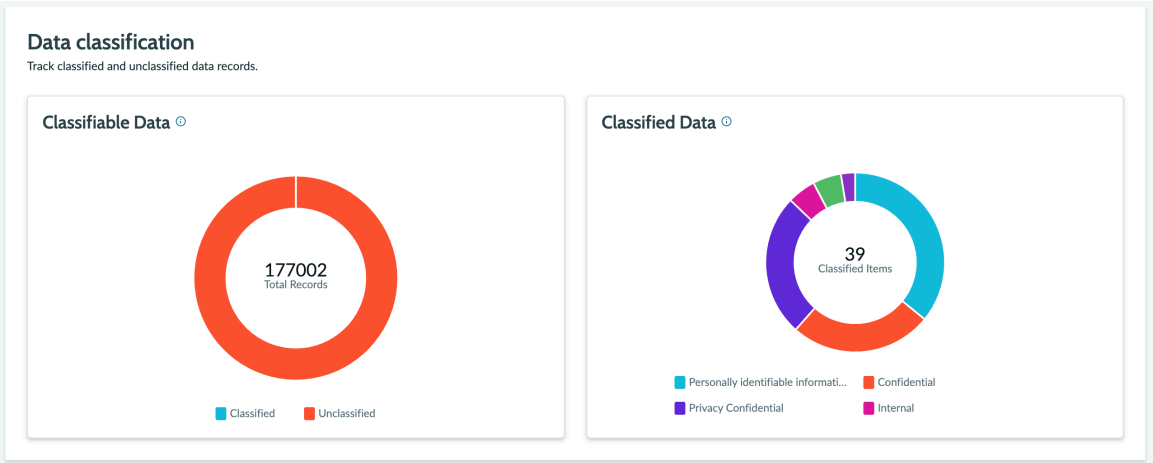
Basic metrics

You can view several basic privacy metrics at the top of the display.

Basic privacy metrics

Metric	Description
Records anonymized by job	Data in tables and column in the instance anonymized using job and user based anonymization policies.
Real time records anonymized	Data in transit (via tables/columns and real-time channels) to the instance, anonymized using real-time anonymization policies).
Alert submissions	Notifications provided to users when sensitive data is detected in a field.
Blocked submissions	Data entry submissions prevented due to sensitive data blocking policies.
Quarantined attachments	Attachments containing sensitive data that have been isolated from the system for security review.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



You can choose to sort the information with the time dropdown, to any of the following views:

- Last 7 days
- Last 30 days
- Last 90 days
- All time

Select **View more data** underneath any metric to review it in more detail.

Data classification

Displays information on data records.

Data classification charts

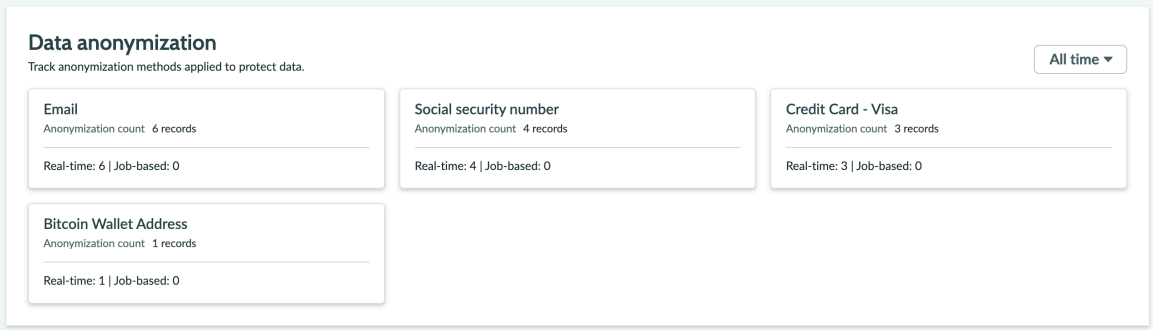


Chart	Description
Classifiable data	• The total number of data records in the instance that can be classified. • The number is broken down into the total number of classified data and the total of unclassified data. • Gives administrators a quick view of potential classification opportunities.
Classified data	• The total number of data records in the instance that have been classified. • The number is broken down into the total number of classified data for each assigned data class. • Provides a quick understanding how much data has been classified in each area.

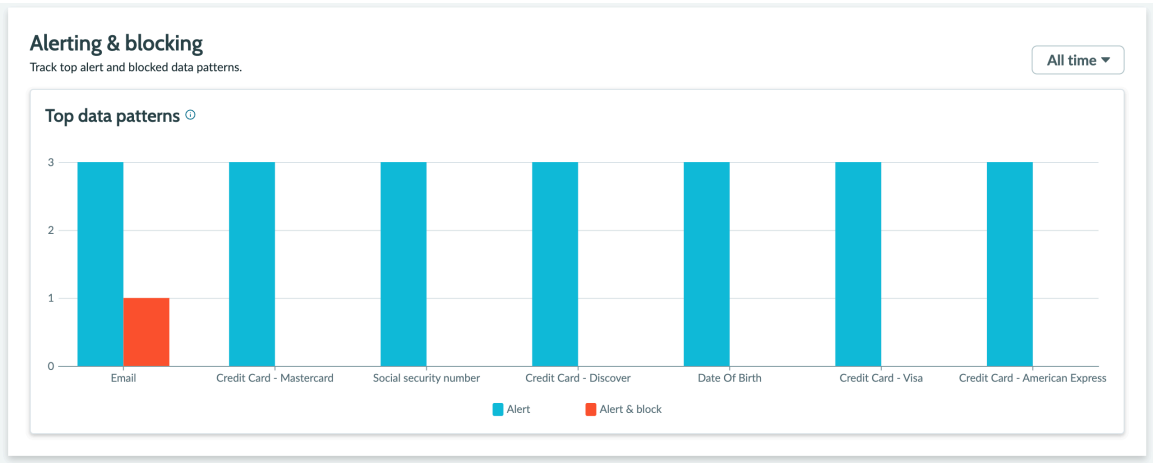
Data anonymization

You can track anonymization methods applied to protect data.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note: The metrics displayed here apply to real-time anonymization and job-based anonymization when the data pattern anonymization technique is selected. Both real-time anonymization and data pattern anonymization configurations make use of active data patterns, as defined in **ALL > System Security > Data Discovery (Classic) > Active Data Patterns**.

Each metric provides the following information on its data pattern:



- Total number of anonymizations for this data pattern
- The number of real time anonymizations for this data pattern
- The number of job-based anonymizations for this data pattern

You can choose to sort the information with the time dropdown, to any of the following views:

- Last 7 days
- Last 30 days
- Last 90 days
- All time

Alerting and blocking

You can track top alert and blocked data patterns.

The chart shows the most frequently detected types of sensitive information found during data discovery scans. It shows whether the information was alerted or blocked.

You can choose to sort the information with the time dropdown, to any of the following views:

- Last 7 days
- Last 30 days

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Last 90 days
- All time

Other resources

For additional information on how to get started securing your instance with data privacy, you can access additional product learning resources about classification or anonymization on the right, including links to videos, documentation, and FAQs.

Data classification

Group data by type, using pre-defined or user-defined data classifications. If you have an assigned data classification administrator or auditor role, you can administer different data classes or visually analyze the current state of different types of data within the instance.

Data Classification enables support for:

- Visibility into the types of data hosted on a ServiceNow AI Platform instances.
- Compliance with privacy laws, and meeting regulation requirements for industries such as financial services and medical device manufacturing.

Data classifications

Data classification is a standalone process in which you manually apply data classifications to existing dictionary entries in any table. See Data dictionary tables for additional information.

- You classify data as you find appropriate for your business and you can alter the available data classes as necessary.
- When you classify data, you can use the pre-defined data classifications, or create your own. Although use of pre-defined data classifications is optional, it is advisable do so as a starting point. These pre-defined data classifications are included in demo data that you can install in your instance.
- If you create your own data classifications, you can also design a tiered hierarchical system with parent and child data classifications.

Note: Data Classification supports domain separation, and the data_classification table itself is process separated. See Domain separation and Data Classification for additional information.

Use cases

General Data Protection Regulation (GDPR) is a European Union regulation whose purpose is to provide individuals with control over their own personal data. You can use data classifications, such as Personally Identifiable Information, to identify where personal data is being stored in your instance. By applying the appropriate security mechanisms to protect that personal data from leaking out, your organization satisfies GDPR requirements.

If you store customer information in the ServiceNow AI Platform, use the Personally Identifiable Information (PII) classification code where needed to track data subject to regulation by local privacy laws.

You can apply a Restricted data classification to Employee table columns that store sensitive employee information such as Social Security Numbers (SSN). Administrators and auditors can then use the Overview dashboard to confirm that you have assigned data classifications to the correct columns. They can also view the classification details for restricted types of information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Create data classifications

Create your own user-defined data classifications in the [data_classification] table that you can then assign to specific columns in specific tables. Create new data classes to start the classification process.

Before you begin

Role required: data_classification_admin, admin

Procedure

1. Navigate to **All** > **System Security** > **Data privacy** > **Classification**.
2. Select **+Add data class**.

   Note: There are several data classes included with the base system.

3. Fill in the fields on the form.

Field	Description
Class Name	Name of the data classification.
Parent Class	Name of the parent data classification that this data classification is subordinate to. Leave the field empty if this data classification isn't a child to a parent data classification.
Description	Description of the data classification.

4. Click **Submit**.
   The new data class is added. If the data class is a child, it will be listed under the parent in the left-hand navigation bar.

Classify data

Group data by type, using pre-defined or user-defined data classifications. Assign data classifications to specific table columns in the Dictionary [sys_dictionary] table. When you assign data classifications, it creates entries in the Dictionary-Data Class [m2m_dictionary_dataclass] table, which you can then review in the Overview dashboard.

Before you begin

Role required: data_classification_admin, admin

Procedure

1. Select **New** to assign data from a table to be classified.
2. Select the data class from the drop-down.
3. Select the records reflecting the tables and columns to be classified.
   Choose additional rows to display per page in the table to simplify locating a particular table.
4. Select **Classify data**.
   The data is classified under the Classification Name in the Classified Data table.
5. View or export the data to Excel, CSV, JSON, or PDF.
   Choose to download the data in the chosen format or receive it via email.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data anonymization

Anonymization provides a way to easily transform data so that it is unidentifiable and more compliant with data privacy regulations.

Administrators can perform the anonymization process in both production and non-production instances. Data privacy can be used in production instances to de-identify users. Anonymization of data classes should only be used with non-production instances. This preservation ensures that data like email addresses or physical addresses are replaced with similarly formatted, but anonymized versions.

Administrators can also use anonymization as part of their General Data Protection Regulation (GDPR) Right to be forgotten (RTBF) processes to anonymize user information. See https://gdpr-info.eu/art-17-gdpr/ for more information.

Use the anonymization section of data privacy to create and view privacy policies and techniques,and to perform privacy bulk assignment. View all of the jobs, with the description, private policy used, and status. In order to access the anonymization section, an admin must first elevate to the data_privacy_admin and data_privacy_processor roles.

Anonymization techniques

Anonymization techniques are options you select to determine how your data is anonymized. You must create an anonymization technique to reference in the anonymization job. See Create anonymization techniques to associate a privacy technique to an associated **Anonymization technique configuration**.

Anonymization policies

Configure an anonymization policy to specify which data privacy techniques are used when anonymizing your data. See for Create anonymization policies details.

Anonymization jobs

Anonymization jobs use all of these components to anonymize your data. For more information on these jobs, see Create anonymization job.

Create anonymization techniques

Create a data privacy technique configuration to customize how data privacy anonymizes your data.

Before you begin
Role required: data_privacy_admin and admin

Procedure

1. Elevate to the **data_privacy_admin** role.
   For details on role elevation, see Elevate to a privileged role.
2. Navigate to **System Security** > **Data Privacy** > **Anonymization**.
3. Select **View techniques**.
   There are several pre-defined techniques available for selection.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Technique	Description
Selective Replace	This technique does a selective replace of String data. All characters between the input's start and end indices are replaced with the character you choose. You can specify characters to exclude from masking: ○ start_index: Technique masks data starting at the specified character. If left blank, masking begins with the first character. ○ end_index: Technique masks data from the start of the string to the specified character. If left blank, masking ends with the last character. ○ exclude_char: Define a character to exclude from masking. ○ replacement_char: Define a character used for masking. If none is provided, asterisks(*) are used by default.
Static Replace	This technique swaps values with static values. String, Number, and Date data can use this technique: ○ date_time_value: Replace Date values with this date. Use the yyyy-MM-dd HH:mm:ss format. ○ date_value: Replace Date values with this date. Use the yyyy-MM-dd format. ○ number_value: Replace Number values with this number. ○ string_value: Replace String values with this text. ○ number_type: Accepts an integer number
Random Replace	This technique swaps values with randomly generated values. String and Number data can use this technique.
Remove	This technique removes values, replacing them with empty (null) values.
No Action	This technique is a placeholder. It does not modify fields when selected.
Selective Replace with X	Transforms String data and selectively replaces sensitive characters with the letter X. **Note:** Default technique for data patterns in Exploring Data Discovery (Classic).
Data pattern anonymization	Only anonymizes discovered data patterns within unstructured data fields while keeping underlying context intact. **Note:** Settings for this technique reference data pattern anonymization technique settings in Exploring Data Discovery (Classic).

4. Select **Add custom technique**, if not using a pre-defined technique.
5. Fill in the fields in the **Customize technique** form.

Field1	Description
Base technique	Select a pre-defined technique, as custom techniques are based on the pre-defined techniques.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field1	Description
Technique name	Enter a name for the technique.
Technique description	Enter a description for the technique.

6. Select **Next**.
7. Enter the technique parameters.
   The available parameterized values depend on which privacy technique you have selected. There are no parameterized values for the **No Action** and **Remove** techniques.

Privacy parameterized values for the Base techniques

Base Technique	Privacy Technique Parameter value	Description	Default value
Selective Replace	end_index	Technique masks data from the start of the string to the specified character. If left empty, masking ends with the last character.	(Empty)
Selective Replace	exclude_char	Character to skip masking. Only a single character can be used in this value. If more than one is entered, the first character is used.	(Empty)
Selective Replace	replacement_char	Character to use when replacing values using a selective replace.	An asterisk (*) is used if no other value is entered.
Selective Replace	start_index	Technique masks data starting at the specified character.	If left blank, masking starts at the first character.
Static Replace	date_time_value	Replace date and time values with this date. Use the yyyy-MM-dd HH:mm:ss format.	1988-11-11 10:10:10
Static Replace	date_value	Replace date values with this date. Use the yyyy-MM-dd format.	1988-11-11
Static Replace	number_value	Replace Number values with this number.	1234567
Static Replace	string_value	Replace String values with this text.	TEXT123

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Base Technique	Privacy Technique Parameter value	Description	Default value
Random Replace	preserve_data_length	Set to **true** to preserve data length. De-identified data will have the same length as the original data.	True

8. Select **Create Custom Technique**.
   Your custom technique is added to the Anonymization techniques.

What to do next
See Create anonymization policies to configure an anonymization policy to specify which techniques are used when anonymizing your data.

Create anonymization policies

Configure an anonymization policy to specify which techniques are used when anonymizing your data.

Before you begin
The data privacy configuration defines tables, `sys_user` and columns to anonymized information, depending on the use case and specific parameterized types of the techniques used.

Note: To complete a privacy configuration, you must first configure a data privacy technique configuration. See Create anonymization techniques for more information.

Role required: data_privacy_admin and admin

Procedure
1. Elevate to the **data_privacy_admin** role.
   For details on role elevation, see Elevate to a privileged role.
2. Navigate to **System Security** > **Data Privacy** > **Anonymization**.
   All anonymization policies display. Published policies are available to schedule the anonymization job.
3. Select **Create new policy**.
4. Select to either anonymize **Data tables or columns**, **User specific data**, **Catalog variable**, or **Real-time data**.

Data Type	Description
Data tables or columns	Records that match the data policy will be anonymized.
User specific data	Select a set of users or user groups to be anonymized.
Catalog variable	Anonymize sensitive data stored in catalog item variables and form fields.
Real time data	Anonymize real time entries for a set of columns.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data privacy policies can only apply to classified data, for more information on data classification, see Data classification.

5. Select **Create**.
   There are sequential steps required to complete the policy. You must **Define details** and **Assign techniques**. **Select user reference** is also required when defining the policy for user specific data.

   For catalog variables, you will **Define details** and select the scope (either **Service catalog request** or **Record producer**), then review the **Data pattern anonymization**.

   Note: Data pattern anonymization uses the information currently in the active data pattern table.

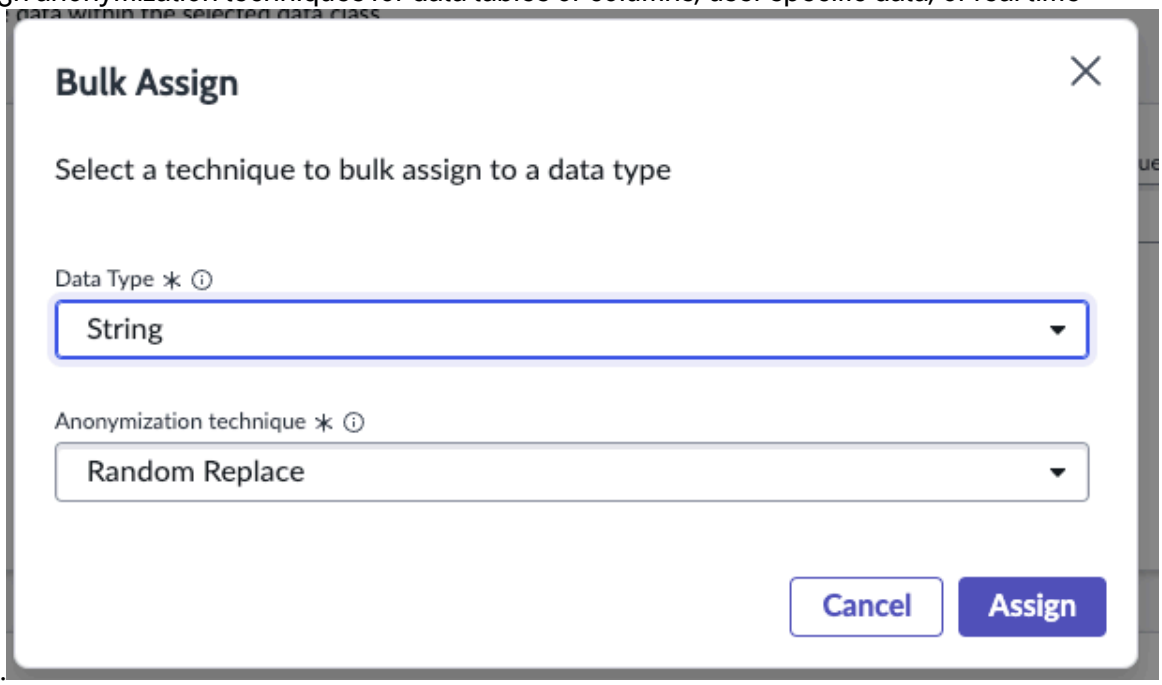
6. Define the details for the new anonymization policy, which will vary depending on the chosen data type.
   - Enter the policy name in the **Name** field, and the policy description in the **Description** field.
   - Define what channels automatically activate the policy and the channel priority in **Activation Channels**
   - In the **Data to process** field, select the data class to use with this policy.
   - If you're configuring real-time anonymization, you can select specific child tables from different scopes to include in your anonymization policy. Enter their columns in this field, then select the child tables in the following menu.

   Note: If you are not anonymizing an entry, select the **DoNothing** technique rather than leaving the entry empty. Policies with empty values in the Privacy Technique Configuration field cannot execute when used in data privacy jobs.

7. Select **Continue** to move to the next configuration step.

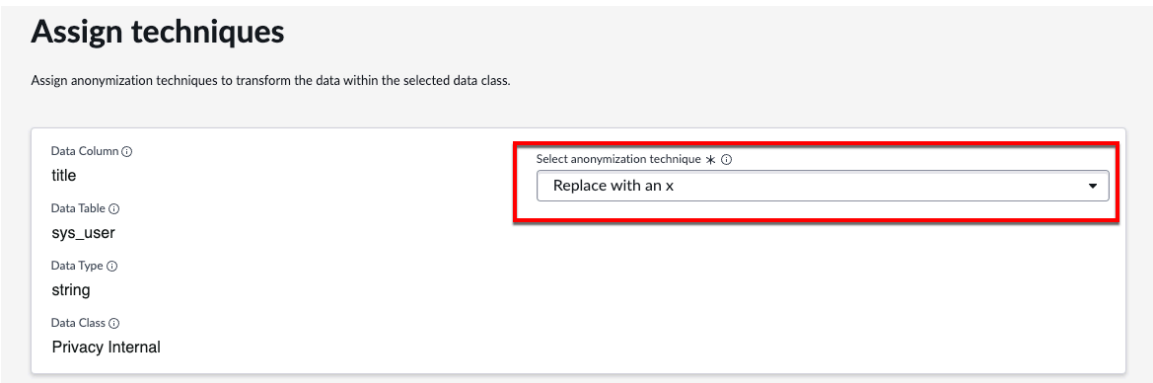
Assign data anonymization techniques

Assign anonymization techniques for data tables or columns, user specific data, or real time data.



About this task

Role required: data_privacy_admin and admin



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Assign anonymization techniques for data tables or columns, user specific data, or real time data.

Option	Description
Select Bulk Assign Techniques	Applies anonymization to all data records in the chosen data class. Select the data type and the anonymization technique to apply to all entries with the selected data type. Repeat this step for additional bulk assignments of different data types. See Supported field types for anonymization for a list of data types.
Select an anonymization technique for each data column record	Your data privacy processor users can choose which records to anonymize when creating data privacy jobs. Individually apply anonymization to each data record in the cho sen data class.

2. **Optional:** Enter child tables to be scanned.
   Child tables of the parent will be anonymized, if a table has no children this option will not be available.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Warning: A parent job will fail if a child job fails.

3. **Optional:** If Data Pattern Anonymization is selected, select the anonymization technique to be used.
4. **Optional:** Set the ordering for data patterns.
5. **Optional:**

   Tip: Use the **Test** feature to test sample inputs. You can review metrics from the result like scan time, result, and discovered patterns.

   Select the **Test** button to test the policy.

6. **Important:** All tables must have a correct sys_dictionary entry.

   Select **Save**.
7. Select **Publish** to update the anonymization policy for scheduling and be returned to Anonymization policies.

   Note: Only published policies can be used for anonymization job scheduling.

What to do next
Create anonymization job.

Configure data anonymization clone request

Data privacy clone integration is configured using a PostClone script to create and execute data privacy jobs for configured policies on the target. After running the script, users will see de-identified data and will not have access to the original data.

Before you begin
The data privacy PostClone script is installed with the activation of the data privacy plugin (sn_dp_store_app). See Activate data privacy for details.

Role required: data_privacy_clone_processor, data_privacy_admin, and admin

Procedure
1. Activate the data privacy plugin (sn_dp_store_app) on the source instance.
   The data privacy PostClone script is installed.
2. Elevate to the **data_privacy_admin** role.
   For details on role elevation, see Elevate to a privileged role.
3. Navigate to **System Security** > **Data Privacy** > **Anonymization**.
4. Select **Create new policy**.
   See Create anonymization policies for details.
5. Select **Data tables or columns**.
6. Select **Create**.
7. Enter a name and select a data class.
8. Select to **Activate the policy during cloning**.
9. Select the policy order to run if there are multiple clone policies.
   A data privacy job for Postclone configuration with a higher Application Order might start before another job of lower order, if the job with the higher order does not involve any table related to other lower order job.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

10. Select **Continue**.
11. Complete the policy configuration and publish the policy.
12. Back up data privacy configurations.
13. Schedule the anonymization job.
    See Create anonymization jobfor details.
14. As the data privacy admin, submit a clone request.

Result

The data privacy PostClone script executes on the target Instance and The PostClone script creates a data privacy federated job record on the target instance. The federated job creates and executes a data privacy job for each post-clone policy, in Application Order, on the target instance.The backup source is cloned to the target Instance. Data privacy PostClone script creates and executes data privacy jobs for configured policies on the target instance.

The elevated data privacy clone processor can log on to the target instance and monitor the post-clone federated job state on the dp_federated_job.list and dp_job.list.

Create anonymization job

Configure a data privacy job on your production instance to use anonymized data on your non-production instance for user and data class jobs.

Before you begin

The data privacy job supports two de-identification use cases:

- Sensitive data of specific sys_users
- Sensitive data of particular data class.

Role required: data_privacy_processor and admin

Procedure

1. Elevate to the **data_privacy_processor** role.
2. Navigate to **System Security** > **Data Privacy** > **Anonymization**.
3. In an Anonymization policy, select **Schedule job** for the policy to be used in the job.
   A policy must be in a published state in order to schedule an anonymization job.

> ⚠ **Warning:** Anonymization jobs are highly destructive and can only be reversed on rollback. Double check all information and consider executing dry runs before scheduling an anonymization job.

4. In the form, fill in the fields.

Data privacy job fields

Field	Description
Policy used	Read only name of the selected privacy policy configuration to use for this job. Edit the policy to view additional information about the policy. For detail on privacy policy configurations, see Create anonymization policies.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Job description	Description of the job.
Start time	The start of the time to run this job in **HH:MM:SS**.
End time	The end of the time window to run this job in **HH:MM:SS**. The end time must be after the start time. The job runs before the time entered in this field. If the job has not yet completed, the job will pause and resume at the next time window start.
Type of user selection	Select either users or groups to be anonymized. **Note:** This required field displays only when the selected privacy policy condition requires a selection of user records.
Select users/groups	Select the specific set of users or groups to be anonymized in this job. Supports up to a maximum of 1000 users. **Note:** This required field displays only when the selected privacy policy condition requires a selection of user records.

Important: All tables must have a correct sys_dictionary entry before scheduling and during its job.

5. **Optional:** Add conditions to specify which data should be anonymized.

   (Optional) This does not apply to cloning anonymization policies.

   Note: For recurring jobs, tables with defined conditions will run a full scan each time the job executes.

   Select the table fields you want to apply a condition to, a boolean operator for the field, and the condition value. You can add multiple conditions with the **Or** and **And** buttons, or delete the condition entirely by selecting the delete icon.

6. **Optional:** Choose whether to run this job in Preview mode by selecting the **Dry run** toggle.

   (Optional) You can run a preview of the anonymization job to see exactly how your data will be anonymized before committing your changes. This creates a temporary preview that auto-deletes after 72 hours. No actual data will be modified.

   Choose between:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Sample preview** - Uses a sample scan on up to 1000 records. Faster to generate, best for a quick initial check.
- **Detailed preview** - Uses a full scan on all records in scope. Takes longer, but reflects actual anonymization results more accurately.

The Dry Run capability has the following considerations and limitations to be aware of:

- Dry run preview does not work for anonymization of encrypted columns.
- There is an upper limit of 200k records per table.
- Sample dry run - 10 preview records per column are allowed.
- Detailed dry run - 10 preview records per data pattern per column are allowed; for data pattern anonymization, the limitation is `10 *` the number of active data patterns.

7. Select **Schedule job** on the form to place the anonymization in the job queue.

The job runs between the times selected in the **Start time** and **End time** fields. If the job has not completed during the start and end time window, the job will continue at the next time window start.

A job can only be executed once, even if **Dry Run** is selected. To run a job again based on the same policy, select **Schedule job** and complete the form using the same field values.

⚠ **Warning:** Anonymization jobs on encrypted columns will decrypt and re-encrypt any encrypted columns targeted by the job. To prevent this, select **No Action** as the policy technique.

The job is listed in the **Jobs** pane.

Field	Description
Name	Name of the anonymization job.
Description	Description of the anonymization job.
Updated	The date and time that the job was last updated.
State	State of the data privacy job: ○ **Scheduled**: Default state for new jobs. ○ **Completed**: The job has successfully anonymized the selected data. ○ **Cancelled**: The job was manually cancelled. ○ **Error**: There was a problem saving the job. Re-schedule the job or create a new job. There may be issues with the configuration if the error continues. ○ **Rollback in progress**: The job has been set to roll back anonymization. ○ **Rollback complete**: The anonymization job rollback has successfully completed. A read-only field.

8. Select a job from the **Jobs** pane to open the Job summary.
After a job is scheduled, the **Cancel Job** and **Pause** buttons appear in the Job summary.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Additional fields for scheduled jobs

Field	Description
Estimated record count	The estimated number of records this dry-run job affects before being executed. A read-only field
Total data records processed	The total number of individual data records affected by this job. A read-only field.
Total data tables processed	The total number of data tables processed by this job. A read-only field.
Time remaining to rollback	The remaining time that a completed data anonymization job can be rolled back and de-anonymize the data. A read-only field.
Total users processed	The total number of individual user records this job affects. A read-only field.
Cancel job	Select to cancel the anonymization job. This must be selected prior to the job start time. When selected, the job status updates to *Cancelled*.
Pause	Select to pause the job and rollback recording, if rollback was selected. A warning message will display after a three-day expiry period for rollback contexts. This must be selected after the job start time and before the job end time. When selected, the job status updates to *Paused*.
Resume	Restarts a paused job. Rollback is not supported for resumed jobs if paused. Cancel the job and create a data privacy job. The recording uses an unexpired rollback context. When selected, the job status updates to *Scheduled*.
Export	Downloads a .PDF file of the data privacy job details.

Activate parallel jobs for data anonymization

Use parallel jobs to reduce your anonymization job execution time.

Before you begin

Role required: admin

Procedure

By default data class and user based anonymization jobs run using a single thread. Multiple threads may be activated for data class and user based jobs. In addition, federated jobs used during cloning uses parallel jobs with 3 workers by default.

1. In the navigation filter enter `sys_properties.list`.
2. Create the property `com.glide.data_privacy.max_parallel_workers`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. **Optional:** To adjust the number of federated job parallel workers, edit the `dp.max_concurrent_clone_item_workers` property.
4. Verify the **Type** is `integer`.
5. **Important:** It is recommended to start with a small number of workers per node(2 or 3).

   Enter the number of parallel job workers in the **Value** field up to 5.

Bring Your Own PII Detection Service

Integrate your organization's PII detection service to discover and mask sensitive data during AI inference calls. Routing your sensitive data inline guardrails to an external service allows you to comply with legal requirements around AI & Data Governance.

ServiceNow's Bring Your Own PII Detection Service feature enables organizations to connect their custom PII (Personally Identifiable Information) detection services to the ServiceNow Data Privacy module. Instead of relying solely on built-in detection patterns, you can configure external detection services to analyze data according to your organization's specific compliance requirements and detection rules.

Important: This capability does not apply to sensitive data sitting on the platform. Instead, it applies to ServiceNow Otto inline guardrails for detecting and masking sensitive data, which are part of Now Assist Guardian capabilities. To leverage this capability, you need a Data Privacy or ServiceNow Vault license.

The Bring Your Own PII Detection feature allows you to:

- Configure one or more external PII detection services
- Set a default external service configuration per channel
- Test external service connections to verify functionality
- Activate and deactivate external services without removing configurations
- Manage multiple external detection services from a centralized home page

Key concepts

The following concepts are fundamental to understanding and using the Bring Your Own PII Detection Service feature:

- **External service configuration:** A connection definition that specifies the endpoint, credentials, and settings for your custom PII detection service.
- **Channel:** A communication pathway through which PII detection requests are routed.
- **Default configuration:** The external service configuration that is automatically used for a specific channel when no other configuration is explicitly selected.
- **Service state:** Whether an external service configuration is active (enabled for requests) or inactive (disabled from receiving requests).
- **Test functionality:** A mechanism to verify that your external service is responding correctly and can process PII detection requests as expected.

Managing external services

The Bring Your Own PII Detection home page provides a centralized location for managing all configured external services. From this page, you can:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- View a list of all external service configurations with their current status (active or inactive).
- Create new external service configurations.
- Edit existing configurations to update connection details or settings.
- Test configurations to verify functionality.
- Activate or deactivate services without permanently removing configurations
- View detailed information about each service configuration in a side pane.

  The side pane provides additional details about a selected service, including its current state, channel associations, and configuration parameters.

Best practices

- **Test before production:** Always test external service configurations in a non-production environment before deploying to production.
- **Monitor service health:** Regularly verify that your external detection service is responding correctly and processing requests within expected timeframes.
- **Document configurations:** Maintain clear documentation of your external service configurations, including endpoint details and any custom detection rules.
- **Set clear defaults:** Establish default configurations for each channel to ensure consistent PII detection behavior.
- **Plan for failover:** Consider configuring backup external services if your PII detection requirements are critical to your operations.

Requirements

To use the Bring Your Own PII Detection Service feature, you need:

- A valid Data Privacy standalone license (or ServiceNow Vault license)
- An external PII detection service endpoint (URL and authentication credentials)
- Sufficient permissions to create and manage external service configurations
- Knowledge of your external service's API contract (request/response format)

Create an external PII detection service configuration

create external PII detection service configuration to connect your custom detection service to ServiceNow.

Before you begin

Before you begin, verify you have:

- Access to the Data Privacy module
- The endpoint URL for your external PII detection service
- Authentication credentials (API key, username/password, or OAuth tokens) for your external service
- Documentation of your external service's API contract (request and response formats)

Role required: data_privacy_processor and admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **System Security** > **Data Privacy** > **Anonymization**.
2. Select **External Anonymization Services**.
3. Select **Create new service** to create an external service configuration.
   The creation form opens in a modal or page, depending on your deployment.
4. Enter a descriptive **Service label** for your external service configuration.
   This will also be the **Service name**.
5. Write a script to shape the request sent to your service, and map its response back into ServiceNow's format.
   The interface contains additional guidelines to follow.
6. Configure the authentication details for the external service.
   Different external services require different authentication approaches. Consult your external service's documentation for the correct authentication details.
7. Select **Active** if you want to enable the external service policy.
8. Select Default to make the policy the automatic destination for all matching channel calls.

   Note: Only one external service policy can be set as default.

9. Select **Test Connection** to initiate a test of the external service.
   Enter sample text for the test, then select **Run test**. The system sends a test request to the external service endpoint to verify connectivity and basic functionality.
10. Wait for the test to complete and review the test results.
    - If the test is successful, you should see a confirmation message indicating the external service is accessible and responding correctly. Select **OK** to return to the configuration screen.
    - If the test fails, review the error message to diagnose the issue (connection timeout, authentication failure, invalid endpoint, and so on). Select **Edit connection**
11. Once you have successfully tested the connection, select **Publish** to create the external service configuration.
    The new configuration is now available in the **External anonymization services** home page.

Tokenization

Tokenization masks sensitive data for unauthorized users using tokens, and stores a mapping of those tokens to the original data on the instance. Users with authorized roles can retrieve the original data by prompting within the ServiceNow Otto panel.

Tokenization addresses scenarios where organizations need to:

- Anonymize sensitive data in a format-preserving manner that maintains data utility
- Protect sensitive information visible in user interfaces and reports
- Allow authorized high-privilege users to view original data when needed (e.g., incident investigation)
- Maintain detailed audit trails of who accessed sensitive data and when
- Support compliance requirements that may later require data restoration

Tokenization uses cryptographic keys to create a deterministic mapping between original sensitive values and their tokenized equivalents. The original values are securely stored and can only be accessed by users with the appropriate detokenization permissions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Key concepts

- **Tokenization:** The process of replacing sensitive data with a token (a substitute value) while maintaining a reversible mapping.
- **Detokenization:** The process of converting a token back to its original sensitive value, available only to authorized roles.
- **Tokenization policy:** A configuration that defines which data entities (fields, patterns) are tokenized and how the tokenization is applied.
- **Data pattern:** A specific type of sensitive information that the policy targets (e.g., credit card numbers, social security numbers, email addresses).
- **Format preservation:** The property of tokenization that maintains the format and structure of the original data (e.g., a 9-digit social security number remains 9 digits after tokenization).
- **Cryptographic key:** The secret key used to create and verify the token-to-value mapping, ensuring only authorized systems can generate or reverse tokens.
- **Child table tokenization:** Applying tokenization rules to data in related child tables independently from the parent table, maintaining separate tokenization contexts.

How tokenization works

Tokenization follows these principles:

1. **Token Generation:** When a tokenization policy is activated, sensitive data matching the defined patterns is replaced with deterministic tokens. The same original value always produces the same token.
2. **Mapping Storage:** The mapping between original values and tokens is securely stored with the cryptographic key used for generation.
3. **Real-Time Processing:** For real-time tokenization, data is tokenized as it is accessed or displayed, based on the user's permissions.
4. **Authorized Access:** Users with detokenization permissions can request to view original values. This access is logged and audited.
5. **Format Preservation:** The tokenization process maintains the format of the original data, ensuring applications and reports continue to function with the tokenized values.

Common use cases

- **Data Protection:** Anonymize sensitive customer or employee data in incident records or support tickets while allowing escalations to management when needed.
- **Compliance:** Meet regulatory requirements (GDPR, HIPAA, CCPA) by restricting who can see sensitive data while maintaining the ability to restore it for legitimate purposes.
- **Development and Testing:** Use tokenized production data in development environments without exposing real sensitive information, while allowing specific users to restore data when necessary for debugging.
- **Multi-Tenant Scenarios:** Prevent tenant administrators from viewing data of other tenants unless they have explicit detokenization permissions.
- **Audit and Investigation:** Allow security and compliance teams to tokenize data in logs while enabling privileged investigators to view original values when investigating security incidents.

Child table tokenization

Tokenization can be applied independently to child tables without affecting parent table tokenization:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Separate contexts:** Child tables maintain their own tokenization context, allowing different policies for related data.
- **Independent tokens:** The same sensitive value in a parent table and child table can be tokenized differently.
- **Flexible configuration:** Administrators can choose to tokenize parent data, child data, or both, depending on security requirements.

Best practices

- **Principle of least privilege:** Grant detokenization permissions only to users who have a legitimate business need to access the original values.
- **Audit regularly:** Review audit logs of de-tokenization activities to ensure access is appropriate and within policy.
- **Test policies:** Create and test policies in non-production environments before deploying to production.
- **Document your policies:** Maintain clear documentation of what data is tokenized, why, and who can access original values.
- **Monitor child table tokenization:** When using child table tokenization, ensure that the tokenization strategy for related data is consistent with your security posture.
- **Plan for key rotation:** Establish procedures for rotating cryptographic keys while maintaining the ability to access tokenized data.

Limitations and considerations

- Real-time tokenization and detokenization operations consume system resources. Consider the performance impact in high-volume scenarios.
- The security of the tokenization system depends on protecting the cryptographic keys. EnsureTokenization keys are stored securely and access is controlled.
- If tokenized data is used in searches, reports, or exports, ensure your use cases account for the tokenized format.
- While tokenization is format-preserving, certain data types may have constraints on token length or character sets.
- Tokenization only applies to real-time user data entries.
- Once data in a form is tokenized, the ability to edit the field is disabled for all users regardless of whether sensitive data is discovered.
- Selecting **Show sensitive data** is a prerequisite step for users with the elevated role to edit or save the form.

Create a tokenization policy

Create a new tokenization policy to define which sensitive data should be anonymized through reversible tokenization.

Before you begin

Before you begin, ensure you have:

- Access to the Data Privacy module
- Permissions to create tokenization policies
- Identified the sensitive data entities and patterns you want to tokenize
- Knowledge of which roles should have detokenization permissions

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Role required: data_privacy_admin and admin

Procedure

1. Navigate to **System Security** > **Data Privacy** > **Tokenization**.
2. Click **Create tokenization policy**.
   The policy creation form opens, presenting the policy details section.
3. Enter a descriptive name for the tokenization policy.
   Use a name that clearly identifies what data is being tokenized, such as "Customer SSN Tokenization" or "Medical Record Numbers".
4. Define the policy scope by selecting the table(s) and column name(s) that should be tokenized.
   You can select one or multiple tables and columns. Tokenization will apply only to those specified.
5. Specify which roles are allowed to access de-tokenized (original) values.
   Only users with these roles can see the original sensitive data. Others see only the tokenized values.
6. Select **Continue** to open the **Select child tables** page.
7. If your deployment includes child tables with related sensitive data, configure child table tokenization settings.
   You can choose to tokenize child table data independently, with the same policy, or not at all.
8. Select **Continue** to open the **Data patterns** page.
9. Define the data patterns to be tokenized.
   a. Select one or more data patterns that match the sensitive data in your selected fields (e.g., Credit Card, Social Security Number, Email Address).
   b. Configure pattern-specific settings if available (e.g., pattern matching options, special character handling).
   Data patterns define what constitutes sensitive data within the fields you selected. You can use built-in patterns or create custom patterns.
10. Click **Save** to save the policy as a draft.
    The policy is created but not yet active. It appears in the policy list with a "Draft" status.
11. When ready, click **Publish** to activate the tokenization policy.
    Once published, the policy begins tokenizing data according to its configuration.

Review de-tokenization job summaries

View summaries of de-tokenization jobs, monitor access to original sensitive data, and review audit logs for compliance purposes.

Before you begin

Role required: data_privacy_admin, admin, or users assigned specific roles for viewing de-tokenization job summaries and audit logs.

Procedure

1. Navigate to **System Security** > **Data Privacy** > **Tokenization**.
2. Review the De-tokenization jobs section of the interface.
3. Click on a specific job to view its detailed summary.
   The summary provides the following information:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

De-tokenization job summary

Field	Description
Summary	A brief summary of the findings of the job scan.
Job description	The unique identifier for the job.
Created by	The user who created the job.
Start time	The time the job began running.
End time	The time the job completed.
Preview expiry	The date and time at which the job's preview will expire.

4. Export or download job summaries for compliance reporting if needed.

Real time anonymization

Use the real time anonymization(RTA) policy to anonymize data entries in real time.

Real time anonymization Overview

Users create an RTA policy by selecting real time anonymization in the Anonymization Policies page, and then selecting the appropriate data channel. For example you can use Virtual Agent with real time anonymization: create an anonymization policy with the Virtual Agent selected as its **Data Channel**.

Columns from the target tables may be selected for RTA, whereupon active data patterns are used and their policies applied to any valid record entries to the columns targeted for RTA. If an entry matches an active data pattern its associated anonymization technique will be used for anonymization.

Tip: If you need to change the anonymization technique see Configure Data Discovery patterns.

Real time anonymization failures

If an RTA policy fails, you can review its status with the Real time anonymization failures table.

Real time anonymization failures

Review real time anonymization(RTA) failures.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Security** > **Data Privacy(Classic)**.
2. Review the RTA failures in the table.

Field title	Description
Table Column	The table column the failure occurred in.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field title	Description
Failure Reason	Category of the failures cause.
Failure Reason Details	Short description summarizing the cause of the failure.
Privacy Configuration	The RTA privacy configuration that failed.
Record	The specific record that failed.
Table Name	Table the failure occurred in.
Timestamp	Time of the failure.

Real time protection

Analyze user input in real time at the field level to identify sensitive data and alert users about potential sensitive data entry.

Real time protection overview

You can discover and block sensitive data from user inputs to prevent it from entering the platform, alert users when sensitive data is entered to raise awareness, and leverage sensitive data logs to understand where and who is entering sensitive data. You can also choose to block users from saving this information. The real time protection module contains the following tools:

Real time protection

Real time protection policies	Configure policies to protect sensitive data in real-time through alerts and blocking actions.
Alert data patterns	Create alert data patterns; reusable groups of data patterns that detect and then alert or block sensitive data across your organization.
Attachment quarantine policies	Set policies that scan attachments for sensitive data during user uploads into fields.
Attachment scan findings	Review the findings of your attachment quarantine scans, and work with any quarantined or alerted attachments.

Real time protection policies

You can configure policies to protect sensitive data in real-time through alerts and blocking actions.

Before you begin
Role required: data_privacy_admin

Note: Real-time protection is only enforced for user interactive sessions and not background scripts, integrations or instance data replication.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **System Security** > **Data privacy** > **Real time protection** > **Real time protection policies**.

   Note: Child tables inherit all configurations from parent tables and columns. For example, if a policy is defined on the Task table's description column, then the policy will apply automatically to the Incident table's description column.

2. Select **Create new policy.**

   Note: In order to create real time protection polices, you must first create at least onealert data pattern.

3. Fill in the fields on the form:

Field	Description
Policy name	Enter a descriptive name for this alert policy. This name will help you identify the policy when managing real-time protection rules.
Table	Select the table where alert policies will monitor for sensitive data. Only one table can be selected per policy.
Column	Select the column within the table that will be monitored for sensitive data patterns.
Action	Choose the action to take when sensitive data is detected: ○ **Alert and block** notifies you of the infraction and prevents the action. ○ **Alert** notifies without blocking.
Alert data pattern	Select the data pattern that defines what sensitive data to detect. **Note:** You can create Alert data patterns if none exist.
Display message	Enter the message users will see when their action is blocked. It should be clear and actionable so they understand why the block occurred.

4. Toggle the **Active** button if you want to activate the policy.
5. Select **Create**.
   The new real time protection policy is added.

What to do next

The protection policies you create show in the main view. You can edit or delete them by selecting the appropriate option from their Actions menu. You can also select either of the following buttons under each policy:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Button	Description
View logs	View the top 100 activity logs that contain the most sensitive data from the last month. For more information, refer to User sensitive data logs for more information.
View details	View the configuration of the protection policy. You can also toggle the **Active** button to turn the policy on or off.

User sensitive data logs

You can view the top 100 activity logs for specific real-time protection policies that contain the most sensitive data from the last month.

About this task

Role required: data_privacy_admin

Procedure

1. Navigate to **All** > **System Security** > **Data privacy** > **Real time protection** > **Real time protection policies**.
2. Select **View logs** under the real-time protection policy that you want to view logs for.
3. The report that displays shows the top 100 activity logs from the last month, sorted into the following information:

User sensitive data log

Field	Definition
Table	Table configured in the policy where user sensitive data was detected and alerted or blocked.
Column	Column configured in the policy where user sensitive data was detected and alerted or blocked.
Data pattern	Which sensitive data was alerted or blocked.
User	Username of the user who entered sensitive data.
Action	Which action was taken, either Alert or Block.

Alert data patterns

Before you can define real-time protection policies, you must create your alert data patterns; reusable groups of data patterns that detect and then alert or block sensitive data across your organization.

About this task

Role required: data_privacy_admin

To create a new alert data pattern, perform the following procedure:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **System Security** > **Data privacy** > **Real time protection** > **Alert data patterns**.
2. Select **Create new**.

   Note: There are several data patterns included with the base system.

3. Fill in the fields on the form:

Field	Description
Alert pattern configuration name	Name of the alert pattern configuration.
Select data patterns	Names of the data patterns you want to detect for this alert. You can set a maximum of 10 data patterns.

4. Select **Create**.
   The new alert data pattern is added.

What to do next

The alert data patterns you create show in the main view. You can edit or delete them by selecting the appropriate option from their Actions menu.

Attachment quarantine policies

Manage policies that automatically isolate suspicious attachments for security review and analysis.

About this task

Role required: data_privacy_admin and admin

To create attachment quarantine policies, perform the following procedure:

Procedure

1. Navigate to **All** > **System Security** > **Data privacy** > **Real time protection** > **Attachment quarantine policies**.
2. Select **Create new policy**.
3. Enter a Policy Name for the policy.
4. Toggle the **Active** button on if you want the policy to be enforced.
5. Select **Add table**.
6. Enter the tables you want the policy to apply to.
7. Specify which data patterns you want to monitor for sensitive content in attachments.

   Important: Attachments matching the patterns you define here will be automatically quarantined. Users will receive an **Attachment Quarantined** message indicating the attachment was quarantined due to sensitive data detection, information on the scan result, and instructions for getting their attachment released.

8. Select **Save** to set the table definitions as part of the policy.

   Note: You can define multiple tables for the policy to apply to.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

9. Select **Confirm** to save the policy.
   The new attachment quarantine policy is added on the main view.

What to do next

The attachment quarantine policies you create show in the main view. You can edit or delete them by selecting the appropriate option from their Actions menu. You can also select either of the following buttons under each policy:

Button	Description
View scan findings	View the findings specific to the quarantine scan policy, including links to flagged attachments and their status. **Note:** To work with the findings themselves, including the release of quarantined attachments, refer to Attachment scan findings.
View policy details	View the configuration of the attachment quarantine policy. You can also toggle the **Active** button to turn the policy on or off.

Attachment scan findings

You can review the findings of your attachment quarantine scans, and work with any quarantined or alerted attachments.

About this task

Role required: data_privacy_admin and admin

Procedure

1. Navigate to **All** > **System Security** > **Data privacy** > **Real time protection** > **Attachment findings**.
2. Review the list of attachment quarantine findings. The following information is shown:

Attachment scan findings

Field	Description
Policy	The quarantine attachment policy used in the scan. Select the name of the policy to view it.
Attachment source table	The tables the scan applied to. Select the name of the table to view it.
Record ID	The record produced by the scan. Select the ID of the record to view it.
Attachment	The attachment flagged in the scan. Select the link to view it.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Select the name of the attachment to view it.
Status **Note:** A background job exists that will perform a one-time rescan of any attachments in Pending or Available status. If this rescan fails, the file cannot be downloaded.	The status of the attachment found in the scan. Status options include: ○ **Pending** - Either the file has not yet been scanned for sensitive data or the scan failed because the property `dp.pii.document.download.allowed` is set to `false`. The file is not available to download. ○ **Available** - The file has been scanned and no sensitive data was found. It is available to download. ○ **Available conditionally** - The file failed to scan for sensitive data even though the property `dp.pii.document.download.allowed` is set to `true`. The file can be downloaded even though it has not been scanned. ○ **Quarantined** - The file was scanned and sensitive data was discovered. The file is quarantined and not available to download (until reviewed and approved by an Admin). **Note:** Even if a file has been quarantined, a user may still be able to select the file name as if it were available. However, the attachment will not download and they will see a message indicating that it contains sensitive data.
Data pattern	The confidential information patterns discovered in the scan.

What to do next

You can make quarantined attachments available. To do so, check the boxes of the individual attachments you want to release from quarantine, then select **Mark as available**. If the attachments can be released, a dialog will ask you to confirm. Select **Mark as available** once more to release the attachments to their original locations and allow them to be accessed.

Activate data privacy

Data Privacy includes data classification and anonymization and is installed from the ServiceNow Store.

Before you begin

To use data anonymization, Data Privacy (Classic) must first be activated with the ServiceNow Vault entitlement. See Activate data privacy (Classic) for additional information.

Note: Installing the Data Privacy Store App will auto install the Data Discovery Store App, Data Privacy (Classic) plug-in, and the Data Classification plugin.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All** > **Data Privacy**.
2. Find the application using the filter criteria and search bar.

   You can search for the application by its name or ID. If you cannot find an application, you may have to request it from the ServiceNow Store.

   Visit the ServiceNow Store to view all the available apps, and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.
3. Select a version from the list and select **Install**.

   In the Install dialog that is displayed, any dependencies that are installed along with your application are listed.
4. If you are prompted, follow the links to the ServiceNow Store to get any additional entitlements for dependencies.
5. **Optional:** If demo data is available and you want to install it, select the **Load demo data** check box.

   (Optional) Demo data comprises sample records that describe application features for common use cases. Load demo data when you first install the application on a development or test instance.

   Important: If you don't load the demo data during installation, it's unavailable to load later.
6. Select **Install**.

Domain separation and data privacy

Domain separation is unsupported for data privacy. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: No support

- The domain field may exist on data tables but there is no business logic to manage the data.
- This level is not considered domain-separated.

For more information on support levels, see Application support for domain separation.

Default data privacy configurations

Data Privacy includes out-of-the-box default configurations that automatically activate for licensed Vault customers, providing immediate value without requiring setup. These configurations enable discovery of existing sensitive data and real-time alerting and user logs for new sensitive data entries in specific fields.

The Vault by Default initiative solves a critical adoption challenge: licensed Vault customers often delay implementing data privacy protections because the setup process is time-consuming and requires configuration across multiple product modules. By providing intelligent default configurations, customers derive immediate value from Data Privacy upon Store App installation and license activation—before completing any manual setup.

Default alerting policy

The **default alerting policy** monitors new sensitive data entry in real-time:

- **When:** Activates automatically upon Data Privacy Store App installation for all licensed Vault customers.
- **What:** Detects seven sensitive data types: Email, Social Security Numbers, Dates of Birth, and four major credit card types (VISA, Discover, American Express, Mastercard).
- **Where:** Monitors Task table, Work_notes, and Comments fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **How:** Generates real-time alerts to the users when the sensitive data is detected, without blocking submission. Alerts and user information are logged for administrators to refer to and take action.
- **Value:** Provides immediate visibility into sensitive data flows, enabling quick response and proactive user training

Default discovery job

The **default discovery job** scans existing sensitive data on the instance automatically and sends an email notification to the admin

- **When:** Runs automatically for trial customers and new and existing licensed ServiceNow Vault customers.
- **What:** Scans 10,000 random records using predefined data patterns.
- **Where:** Targets the following tables and respective fields:
  - Incident (description, short_description, comments, work_notes, close_notes)
  - sc_req_item (via sc_item_option_mtom and question_answer)
  - sc_task (comments, work_notes)
  - sn_customer_service_case and interaction (comments, work_notes)
  - sn_hr_core_case and scoped children (comments, work_notes).
- **Frequency:** Runs only once.
- **Value:** Delivers an immediate baseline of sensitive data exposure, establishing the foundation for classification and data governance

Related topics

For more information on individual default configurations, see:

- Default data discovery job — Overview of the default discovery job that scans existing sensitive data.
- Default alerting policy for sensitive data entry — Overview of the default alerting policy that monitors new sensitive data entry.

To learn how to work with these configurations, see the task topics within each feature overview.

Default alerting policy for sensitive data entry

The default alerting policy automatically detects sensitive data being entered into unstructured fields in real-time and alerts administrators, providing immediate visibility into sensitive data flows without requiring configuration.

The default alerting policy is part of the Vault by Default initiative to provide immediate value to licensed Vault customers upon Data Privacy Store App installation. Unlike discovery jobs that find existing sensitive data, the alerting policy monitors data entry in real-time, alerting administrators the moment sensitive information is entered into monitored fields.

The default alerting policy solves a critical visibility gap: licensed Vault customers have limited insight into what types of sensitive data users are entering in unstructured fields (comments, notes, free text fields). By automatically creating and activating an alerting policy upon Store App installation, customers immediately begin receiving alerts about sensitive data flows without any configuration effort.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Key benefit: Real-time visibility into sensitive data entry with zero setup.

Default alerting policy specifications

The default alerting policy includes:

- **Policy type:** Alerting-only (does not mask, redact, or anonymize data)
- **Activation trigger:** Automatic upon Data Privacy Store App installation
- **Target tables:** Task table only
- **Target columns:** Work_notes, Comments
- **Sensitive data patterns:** Email, SSN, Date of Birth, Credit Cards (4 major card types)
- **Action type:** Alert (notification only)
- **Alert recipients:** System administrators
- **User impact:** None—form submission proceeds normally
- **Scope:** Applied to all users entering data in monitored fields

Monitored tables and columns

The default alerting policy monitors the following specific locations on the instance:

Table	Column	Field Purpose
Task	Work_notes	Technician or agent notes added during task resolution
Task	Comments	General comments field on task records

These fields are chosen because they are unstructured, free-text fields where users commonly enter narrative information—and where sensitive data is frequently entered by accident.
